# ON THE CONFIDENCE REGION OF A VECTOR PARAMETER 

JÚLIA VOLAUFOVÁ

## Introduction

Throughout this paper we shall consider the following regression model:

$$
\mathrm{E}_{\theta}(\boldsymbol{\xi})=\mathbf{A} \boldsymbol{\theta}
$$

with $\xi$ an $n$-dimensional random variable. The symbol $\theta$ will denote a $k$-dimensional vector of unknown parameters and the $n \times k$ - type matrix $\mathbf{A}$ is assumed to be known. The covariance matrix of the vector $\xi$ will be denoted by $\Sigma_{\xi}$.

The aim of this paper is to find a confidence region of the vector parameter $\theta$ in such situations in which there would not have to exist any statistics of the form $\hat{f}(x)=L^{\prime} \xi$ possessing the property $\mathrm{E}_{\theta}\left(\mathbf{L}^{\prime} \xi\right)=\theta$ for all $\theta \in R^{k}$. The solutions are given under the constraints $\mathrm{R}\left(\Sigma_{\xi}\right) \leqslant n, \mathrm{R}(\mathbf{A}) \leqslant \min \{n, k\}$ and hence involve also singular situations.

Consequently, there is need for the use of the generalized inverses (g-inverses) as introduced in [4] both with their applications (cf. [2]).

## 1. Preliminaries

Let us consider the model of an indirectly observed vector parameter $\theta$. This model will be denoted by ( $\xi, \mathbf{A} \theta, \Sigma_{\xi}$ ) and $\xi$ will be a gaussian vector.

We shall start with a list of frequently occurring symbols and notations. Given a matrix $\mathbf{A}$, the symbol $\mathbf{A}^{-}$will denote its g-inverse defined by means of the formula $\mathbf{A A}^{-} \mathbf{A}=\mathbf{A}$.

Special cases:
$\mathbf{A}_{\mathbf{m}(\mathbf{H})}^{-}-\mathrm{g}$-inverse satisfying the relations $\left(\mathbf{A}_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}\right)^{\prime} \mathbf{H}=\mathbf{H A}_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}$ the so-called minimum $\mathbf{H}$-norm (seminorm) g-inverse of $\mathbf{A}$
$\mathbf{A}_{\mathbf{1 d}_{(\mathbf{I})}^{-}}^{-}$g-inverse satisfying the relations $\left(\mathbf{A} \mathbf{A}_{1(\mathrm{I})}^{-}\right)^{\prime}=\mathbf{A} \mathbf{A}_{1(\mathbf{I})}^{-}$, the so-called I-least squares $g$-inverse of $\mathbf{A}$;
$\mathbf{A}_{1(\mathrm{I}), \mathrm{m}\left(\mathrm{I}_{\mathrm{k}}\right)}^{-}$- a g -inverse satisfying the relations:

$$
\begin{aligned}
& \left(\mathbf{A} \mathbf{A}_{1(\mathbf{I}), \mathrm{m}\left(\Sigma_{\xi}\right)}^{-}\right)^{\prime}=\mathbf{A} \mathbf{A}_{\mathbf{1}_{(\mathbf{I})}^{-}, \mathrm{m}\left(\Sigma_{\xi}\right)}, \quad \mathbf{A} \mathbf{A}_{1(\mathrm{I}), \mathrm{m}\left(\Sigma_{\xi}\right)}^{-} \mathbf{A}=\mathbf{A}, \\
& \Sigma_{\xi} \mathbf{A}_{1(\mathrm{I}), \mathrm{m}\left(\Sigma_{\xi}\right)}^{-} \mathbf{A}_{1(\mathrm{I}), \mathrm{m}\left(\Sigma_{\xi}\right)}^{-}=\Sigma_{\xi} \mathbf{A}_{1(\mathrm{I}), \mathrm{m}\left(\Sigma_{\xi} \xi\right.}^{-}, \\
& \left(\mathbf{A}_{1(\mathbf{I}), \mathrm{m}\left(\Sigma_{\xi}\right)}^{-} \mathbf{A}\right)^{\prime} \Sigma_{\xi}=\Sigma_{5} \mathbf{A}_{1(\mathbb{I}), \mathrm{m}\left(\Sigma_{\xi}\right)}^{-} \boldsymbol{A},
\end{aligned}
$$

the so-called minimum $\Sigma_{\xi}$-norm (seminorm), I-least squares $g$-inverse of $\mathbf{A}$.
Given a matrix $H$ (of square type and positive semidefinite (p.s.d.)), the symbol $\|\cdot\|_{\mathbf{H}}$ will denote the norm (seminorm) in the Hilbert space with the scalar product $(\boldsymbol{x}, \boldsymbol{y})=\boldsymbol{x}^{\prime} \mathbf{H y}$. Especially if $\mathbf{I}$ is a $k \times k$-type identity matrix, $\|\cdot\|_{I}$ is the usual Euclidean norm in $R^{k}$.

Let us consider a consistent system $\mathbf{A x}=\boldsymbol{y}$. For any matrix $\mathbf{H}$ of the above described type let $\|\cdot\|_{\mathbf{H}}$ be the norm (seminorm) on the set of all solutions of the given system. The solution $x_{o}$ is said to be the minimum H-norm (seminorm) solution provided $\left\|x_{o}\right\|_{\mathbf{H}}=\min _{\{x: \wedge x=y\}}\|\boldsymbol{x}\|_{\mathbf{H}}=\min \left\{\|\boldsymbol{x}\|_{\mathbf{H}}: \mathbf{A x}=\boldsymbol{y}\right\}$. The name for $\mathbf{A}_{\mathbf{m}(\mathbf{H})}^{-}$adopted above is justified by the fact that the vector $\mathbf{A}_{\mathbf{m}(\mathbf{H})}^{-} \boldsymbol{y}$ is a minimum $\mathbf{H}$-norm (seminorm) solution of the system $\mathbf{A x}=\boldsymbol{y}$. The family of all minimum H-norm (seminorm) g-inverses of the matrix $\mathbf{A}^{\prime}$ is denoted by $\left(. \Lambda^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}$.

Definition 1.1. Let $\boldsymbol{p}, \boldsymbol{\theta}$ be two column vectors with the range in $R^{k}$. The linear function $f(\theta)=p^{\prime} \theta$ is said to be unbiassedly estimable iff there is a column vector $L \in R^{n}$ such that $\mathrm{E}_{\theta}\left(L^{\prime} \xi\right)=p^{\prime} \theta$ for all $\theta \in R^{\boldsymbol{k}}$.

Lemma 1.1. [2] $A$ function $f(\theta)=p^{\prime} \theta$ is unbiassedly estimable if and only if $\boldsymbol{p} \in \mathcal{M}\left(\mathbf{A}^{\prime}\right)$, the range of the matrix $\mathbf{A}^{\prime}$.

Definition 1.2. Let $\mathrm{E}_{\theta}(\xi)=\mathbf{A} \theta$, where $\xi$ is an $n$-dimensional random vector. Let $\Sigma_{\xi}$ be its covariance matrix. Any vector $\mathbf{M} \xi$ satisfying the conditions:
(i) $\forall p \in \mathcal{M}\left(\mathbf{A}^{\prime}\right) \forall \theta \in R^{k}: \mathrm{E}_{\theta}\left(\boldsymbol{p}^{\prime} \mathbf{M} \xi\right)=\boldsymbol{p}^{\prime} \theta$
(ii) $\forall p \in \mathcal{M}\left(\mathbf{A}^{\prime}\right)\left[\forall \mathbf{M}_{1} \xi \neq \mathbf{M} \xi\left(\mathrm{E}_{\theta}\left(\boldsymbol{p}^{\prime} \mathbf{M}_{1} \xi\right)=p^{\prime} \theta\right) \Rightarrow\left(\sigma^{2} \boldsymbol{p}^{\prime} \mathbf{M} \xi \leqslant \sigma^{2} \boldsymbol{p}^{\prime} \mathbf{M}_{1} \xi\right)\right]$
is said to be a fictitious jointly effective estimate of $\theta$. Here the symbol $\sigma^{2}$ is used to denote the variance, and $\mathbf{M}$ is an arbitrary matrix of type $k \times n$.

Remark 1.1. The term fictitious should emphasize the following fact. In the case $\mathcal{M}\left(\mathbf{A}^{\prime}\right)=R^{k}$ we have $E_{\theta}(\mathbf{M} \xi)=\theta$ for all $\theta \in R^{k}$. However, if $\mathcal{M}\left(\mathbf{A}^{\prime}\right) \subseteq R^{k}$, there is $\theta_{o} \in R^{k}$ such that $\mathrm{E}_{\theta}(\mathbf{M} \xi) \neq \theta_{0}$, hence $\mathbf{M} \xi$ is not an unbiassed estimate of $\boldsymbol{\theta}_{0}$. On the other hand, when substituting the vector $M \xi$ for the argument of any unbiassedly estimable function $f(\theta)=p^{\prime} \theta$, one gets an unbiassed estimate.

Remark 1.2. Let $f(\theta)=\boldsymbol{p}^{\prime} \boldsymbol{\theta}$ with $\boldsymbol{p} \in \mathcal{M}\left(\mathbf{A}^{\prime}\right)$ (i.e. $f$ is estimable, cf. Lemma 1.1). An estimate $L^{\prime} \xi$ is said to be unbiassed if $\mathbf{A}^{\prime} \boldsymbol{L}=\boldsymbol{p}$. The variance of such an estimate equals $\boldsymbol{L}^{\prime} \Sigma_{\xi} \boldsymbol{L}$. It is natural to conceive an unbiassed estimate $\hat{f}(\xi)=\boldsymbol{L} \boldsymbol{L}^{\prime} \boldsymbol{\xi}$ to be the best if $L^{\prime} \Sigma_{5} L$ is minimal, i.e. if $\|L\|_{\Sigma_{\xi}}$ is minimal.

Theorem 1.1. [2] The best linear unbiassed estimate of an unbiassedly estimable function $f(\theta)=p^{\prime} \theta$ is given by

$$
\hat{f}(\xi)=p^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}\left(\Sigma_{\xi}\right)}^{-}\right]^{\prime} \xi
$$

Remark 1.3. Since the expression in the above theorem is given by means of g-inverses, it is not unique. One of the possible choices is the following one

$$
\boldsymbol{p}^{\prime}\left[\mathbf{A}^{\prime}\left(\Sigma_{\xi}+\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\right]^{-} \mathbf{A}^{\prime}\left[\left(\Sigma_{\xi}+\mathbf{A} \mathbf{A}^{\prime}\right)^{-}\right]^{\prime} \xi
$$

Its variance is given by the formula

$$
\sigma^{2}(\hat{f}(\xi))=\boldsymbol{p}^{\prime}\left[\left(\mathbf{A}^{\prime}\left(\Sigma_{\xi}+\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\right)^{-}-\mathbf{I}\right] \boldsymbol{p}
$$

established in [2].
Theorem 1.2. [2] Let us consider the covariance matrix of the form $\sigma^{2} \mathbf{H}$ with $\sigma^{2}$ an unknown scalar and $\mathbf{H}$ a known matrix, respectively. Let $\hat{\theta}$ be a fictitious jointly effective estimate of $\theta$ (cf. Def. 1.2.). Then the formula

$$
\hat{\sigma}^{2}=(\xi-\mathbf{A} \hat{\boldsymbol{\theta}})^{\prime} \mathbf{H}^{-}(\xi-\mathbf{A} \hat{\boldsymbol{\theta}}) / \boldsymbol{s}
$$

gives an unbiassed estimate of $\sigma^{2}$. Here $s=\mathbf{R}(\mathbf{H}, \mathbf{A})-\mathbf{R}(\mathbf{A})$ and denotes the difference of ranks of the hypermatrix $(\mathbf{H}, \mathbf{A})$ and of the matrix $\mathbf{A}$.

Lemma 1.2. [4] Let $\xi$ be a gaussian vector with a zero mean and the covariance matrix $\Sigma_{\xi}=\Sigma$. Then the quadratic form $\xi^{\prime} \Sigma^{-} \xi$ is $\chi^{2}(k)$-distributed, independently of which $\Sigma^{-}$was chosen, and $k=R(\Sigma)$.

## 2. Confidence Region for the Estimable Functions of a Vector Parameter

Let us consider the model $\mathrm{E}_{\theta}(\xi)=\mathbf{A} \theta$. We shall consider the functions $f(\theta)=$ $\mathbf{P}^{\prime} \theta$ with $\mathcal{M}(\mathbf{P})=\mathcal{M}\left(\mathbf{A}^{\prime}\right)$. It is assumed that $\Sigma_{\xi}=\sigma^{2} \mathbf{H}$.

1. $\sigma^{2}$-known.

Lemma 2.1. The quadratic form

$$
[\hat{f}(\xi)-f(\theta)]^{\prime}\left[\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{P}\right]^{-}[\hat{f}(\xi)-f(\theta)] / \sigma^{2}
$$

is a $\chi^{2}(k)$ - variate with $k=R\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{m(H)}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right)$.
Proof. Follows immediately from lemma 1.2.
To calculate the number $k$ in the preceding Lemma, we have to find a simpler expression for the rank of the matrix

$$
\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{P}
$$

Theorem 2.1. $\mathbf{R}\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right)=\mathbf{R}\left(\mathbf{H}\left(\mathbf{H}+\mathbf{A}^{\prime}\right)^{-} \mathbf{A}\right)$.
Proof. Since $\mathbf{H}$ is p.s.d., there is $\mathbf{J}$ such that $\mathbf{H}=\mathbf{J J}^{\prime}$ (cf. [2]). It was pointed out above that any minimum $H$-norm (seminorm) solution $x$ of the system $A^{\prime} \boldsymbol{x}=\boldsymbol{y}$ has the form $x=\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} y$. Thus we get a family $\mathcal{N}=\left\{\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} y:\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \in\left(\Lambda^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right)$of
solutions. If $\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}}^{-} \boldsymbol{H} \boldsymbol{y}$ is a particular solution, then $\mathcal{N}=\left\{\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}}^{-} \boldsymbol{H} \boldsymbol{y}+\boldsymbol{k}: \boldsymbol{k} \in \operatorname{Ker}\right.$ $\left.\mathbf{A}^{\prime} \cap \operatorname{Ker} \mathbf{H}\right\}$. Consequently $\mathcal{M}\left(\left(\mathbf{A}_{\mathrm{m}(\mathbf{H})}^{\prime} \mathbf{A}^{\prime}\right)=\mathcal{M}\left(\left(\mathbf{A}^{\prime}\right)_{\left(\mathbf{H}_{\mathrm{o}}\right)}^{-} \mathbf{A}^{\prime}\right) \vee\left(\operatorname{Ker} \mathbf{A}^{\prime} \cap \operatorname{Ker} \mathbf{H}\right)\right.$, where $\mathcal{M}\left(\left(\mathbf{A}^{\prime}\right)_{m(\mathbf{H})_{o}}^{-} \mathbf{A}^{\prime}\right) \vee\left(\operatorname{Ker} \mathbf{A}^{\prime} \cap \operatorname{Ker} \mathbf{H}\right)$ denotes the subspace of $R^{n}$ generated by $\mathcal{M}\left(\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}^{\prime}\right) \cup\left(\operatorname{Ker} \mathbf{A}^{\prime} \cap \operatorname{Ker} \mathbf{H}\right)$. Thus the dimension of $\mathcal{M}\left(\mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}^{\prime}\right)$ is invariant for any choice of the g -inverse. One possible choice is the matrix $\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\left[\mathbf{A}^{\prime}\left(\mathbf{H}+\mathbf{A A}^{\prime}\right)^{-} \mathbf{A}\right]^{-}$. Since the matrix $\mathbf{H}$ and the matrix $\mathbf{A A}^{\prime}$ are p.s.d., we have $\mathcal{M}(\mathbf{H}) \subset \mathcal{M}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)$ and $\mathcal{M}(\mathbf{A})=\mathcal{M}\left(\mathbf{A} \mathbf{A}^{\prime}\right) \subset \mathcal{M}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)$, respectively.
It was assumed that $\mathcal{M}(\mathbf{P})=\mu\left(\mathbf{A}^{\prime}\right)$. Therefore there is a nonsingular matrix $\mathbf{Q}$ with $\mathbf{P}=\mathbf{A}^{\prime} \mathbf{Q}$. Substitute for $\mathbf{P}$. Then

$$
\begin{gathered}
\mathbf{R}\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H}}^{-} \mathbf{P}\right)=\mathrm{R}\left(\mathbf{Q}^{\prime} \mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}^{\prime} \mathbf{Q}\right)= \\
=\mathrm{R}\left(\mathbf { A } \left[\left(\mathbf{A}^{\prime}\left[\mathbf{A}_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\right)=\mathrm{R}\left(\mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\mathbf{H}} \mathbf{H}\right),\right.\right.
\end{gathered}
$$

using the idempotence of the matrix $\mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{m(H)}^{-}\right]^{\prime}$ together with its property $\mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}=\mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{A}^{\prime}$ (cf. [4] for a more detailed discussion). Using the equivalences

$$
\begin{gathered}
\mathcal{M}(\mathbf{A}) \subset \mathcal{M}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right) \Leftrightarrow \exists \mathbf{C}: \mathbf{A}=\left(\mathbf{H}+\mathbf{\mathbf { A A } ^ { \prime }}\right) \mathbf{C} \\
\mathcal{M}(\mathbf{H}) \subset \mathcal{M}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right) \Leftrightarrow \exists \mathbf{E}: \mathbf{H}=\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right) \mathbf{E}=\mathbf{E}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)
\end{gathered}
$$

one obtains the relations

$$
\mathrm{R}\left(\mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\right)=\mathrm{R}\left(\mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}^{\prime}\right)=\mathrm{R}\left(\mathbf{E}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{C}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)\right) .
$$

In the latter relation, let us substitute for $\left(\mathbf{A}^{\prime}\right)_{m(\mathbf{H})}^{-}$the choice $\left(\mathbf{H}+\mathbf{A A}^{\prime}\right)^{-} \times$ $\times \mathbf{A}\left[\mathbf{A}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\right]^{-}$. Then

$$
\mathbf{R}\left(\mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}^{\prime}\right)=\mathrm{R}\left(\mathbf{E}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right) \mathbf{C}\left(\mathbf{C}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right) \mathbf{C}\right)^{-} \mathbf{C}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)\right) .
$$

The proof is finished by establishing the relations

$$
\mathrm{R}\left(\mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{A}^{\prime}\right)=\mathrm{R}\left(\mathbf{E}^{\prime}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right) \mathbf{C}\right)=\mathrm{R}\left(\mathbf{E}^{\prime} \mathbf{A}\right)=\mathrm{R}(\mathbf{H C})=\mathrm{R}\left(\mathbf{H}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\right),
$$

which are an immediate consequences of the properties of g -inverses,
Q.E.D.

Remark 2.1. If $\mathcal{M}(\mathbf{A}) \subset \mathcal{M}(\mathbf{H})$, then it follows easily that

$$
\mathbf{R}\left(\mathbf{H}\left(\mathbf{H}+\mathbf{\mathbf { A A } ^ { \prime }}\right)^{-} \mathbf{A}\right)=\mathbf{R}(\mathbf{A}) .
$$

Theorem 2.2. Let $\xi$ be an $n$-dimensional gaussian vector with the expectation $\mathbf{A} \theta$ and the covariance matrix $\sigma^{2} \mathbf{H}$, respectively. Let $\theta$ be an unknown vector parameter. Consider the function $f(\theta)=\mathbf{P}^{\prime} \theta$ with $\mu(\mathbf{P})=\mu\left(\mathbf{A}^{\prime}\right)$. Then the true value of $\mathbf{P}^{\prime} \theta$ lies in the set

$$
\begin{gathered}
\mathscr{V}=\left\{\boldsymbol{y}:(\boldsymbol{y}-\hat{f}(\xi))^{\prime}\left[\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right]^{-}(\boldsymbol{y}-\hat{f}(\xi)) / \sigma^{2} \leqslant \mathrm{c}^{2}\right\} \cap \\
\cap\left\{\hat{f}(\xi)+\mathcal{M}\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right)^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right)\right\}
\end{gathered}
$$

with the probability

$$
\text { Prob }\left\{\chi^{2}(r) \leqslant \mathrm{c}^{2}\right\} .
$$

Here $r=\mathbf{R}\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{(})}^{-} \mathbf{P}\right.$ and $\hat{f}(\xi)$ is the best unbiassed estimate of $\mathbf{P}^{\prime} \theta$.
Proof. By Theorem 1.1., $\hat{f}(\xi)=\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi$. According to Lemma 1.2 and Theorem 2.1.

$$
\begin{aligned}
& \operatorname{Prob}\left\{\left(\mathbf{P}^{\prime} \theta-\hat{f}(\xi)\right)^{\prime}\left[\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P} \mathbf{P}^{-}\left(\mathbf{P}^{\prime} \boldsymbol{\theta}-\hat{f}(\xi)\right) / \boldsymbol{\sigma}^{2} \leqslant \mathbf{c}^{2}\right\}=\right. \\
& =\operatorname{Prob}\left\{\mathbf { P } ^ { \prime } \boldsymbol { \theta } \in \left\{\boldsymbol{y}:(\boldsymbol{y}-\hat{f}(\xi))^{\prime}\left[\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right]^{-}(\boldsymbol{y}-\hat{f}(\xi)) / \boldsymbol{\sigma}^{2} \leqslant\right.\right. \\
& \left.\left.\leqslant \mathrm{c}^{2}\right\}\right\}=\operatorname{Prob}\left(\chi^{2}(r) \leqslant \mathrm{c}^{2}\right) \text {. }
\end{aligned}
$$

On the other hand

$$
\operatorname{Prob}\left\{\hat{f}(\xi) \in\left\{\mathcal{M}\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right)+\mathrm{E}_{\theta} \hat{f}(\xi)\right\}\right\}=1
$$

and hence

$$
\begin{aligned}
& \operatorname{Prob}\left\{\mathbf { P } ^ { \prime } \boldsymbol { \theta } \in \left\{\boldsymbol{y}:(\boldsymbol{y}-\hat{f}(\xi))^{\prime}\left[\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\boldsymbol{( H )}}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{( H )}}^{-} \mathbf{P}\right]^{-}(\boldsymbol{y}-\hat{f}(\xi)) / \boldsymbol{\sigma}^{2} \leqslant\right.\right. \\
& \left.\leqslant \mathrm{c}^{2}\right\} \cap\left\{\hat{f}(\xi)+\mathcal{M}\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right)\right\}=\operatorname{Prob}\left(\chi^{2}(r) \leqslant \mathrm{c}^{2}\right) \text {. }
\end{aligned}
$$

Q.E.D.
2. $\sigma^{2}$-unknown.

Lemma 2.2. Let $f(\theta)=\mathbf{P}^{\prime} \boldsymbol{\theta}, \mathcal{M}(\mathbf{P})=\mathcal{M}\left(\mathbf{A}^{\prime}\right)$ within the regression model $(\boldsymbol{\xi}, \mathbf{A} \theta$, $\left.\sigma^{2} \mathbf{H}\right)$. Let $\boldsymbol{v}=\mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \xi-\xi$ (the vector $\boldsymbol{v}$ is said to be the correction vector). The random variable $\boldsymbol{v}^{\prime} \mathbf{H}^{-} \boldsymbol{v}$ is a $\sigma^{2} \chi^{2}(\mathbf{R}(\mathbf{H}, \mathbf{A})-\mathrm{R}(\mathbf{A}))$-variate.

Lemma 2.3. The vectors $\boldsymbol{v}$ and $\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{(\mathbf{H})}^{-}\right]^{\prime} \xi$ are stochastically independent.
In the proof cf. [1] and [2].
Theorem 2.3. Let $\xi$ be an $n$-dimensional gaussian vector with $\mathrm{E}_{\theta}(\xi)=\mathbf{A} \theta$, $\Sigma_{\xi}=\sigma^{2} \mathbf{H}$. Let $f(\theta)=\mathbf{P}^{\prime} \theta$ be unbiassedly estimable and $\mathcal{M}(\mathbf{P})=\mu\left(\mathbf{A}^{\prime}\right)$. Then the true value of $\mathbf{P}^{\prime} \boldsymbol{\theta}$ lies in the set

$$
\mathscr{W}=\left\{\mathbf{y}: \mathscr{A}(\mathbf{y}) / \mathbf{B} \leqslant \mathrm{c}^{2}\right\} \cap\left\{\hat{f}(\xi)+\mathcal{M}\left(\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right)\right\}
$$

with the probability

$$
\operatorname{Prob}\left(\mathrm{F}(r, \mathbf{R}(\mathbf{H}, \mathbf{A})-\mathbf{R}(\mathbf{A})) \leqslant \mathrm{c}^{2}\right) .
$$

Here

$$
\begin{gathered}
\mathcal{L}(\boldsymbol{y})=(\boldsymbol{y}-\hat{f}(\xi))^{\prime}\left[\mathbf{P}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathbf{m}(\mathbf{H})}^{-} \mathbf{P}\right]^{-}(\boldsymbol{y}-\hat{f}(\xi)) / \boldsymbol{r} \\
\mathbf{B}=\boldsymbol{v}^{\prime} \mathbf{H}^{-} \boldsymbol{v} /(\mathbf{R}(\mathbf{H}, \mathbf{A})-\mathbf{R}(\mathbf{A})) \\
r=\left\{\begin{array}{c}
\mathbf{R}\left(\mathbf{H}\left(\mathbf{H}+\mathbf{A}^{\prime} \mathbf{A}^{-} \mathbf{A}\right) \quad(\text { Theorem 2.1) }\right. \\
\mathbf{R}(\mathbf{A}) \text { if } \mathcal{M}(\mathbf{A}) \subset \mathcal{M}(\mathbf{H}) \quad \text { (Remark 2.1). }
\end{array}\right.
\end{gathered}
$$

To prove the Theorem let us note that the Fisher random variable is the ratio of two stochastically independent (Lemma 2.3) $\chi^{2}$ - variates (Lemma 1.2), each
divided by the corresponding degrees of freedom (cf. Lemma 1.2, Theorem 2.1, Remark 2.1). Otherwise, the proof is similar to the proof of Theorem 2.2.

## 3. Generalization

Let us again consider the regression model $\left(\xi, \mathbf{A} \theta, \sigma^{2} \mathbf{H}\right)$ with $\theta$ an unknown parameter. Now let us suppose that there is at least one column, say $\boldsymbol{e}_{i}$, of the identity matrix I such that $\boldsymbol{e}_{i} \notin \mathcal{M}\left(\mathbf{A}^{\prime}\right)$.

The columns of the identity matrix will be projected onto the manifold $\mathcal{M}\left(\mathbf{A}^{\prime}\right)$; the projections being considered in the Euclidean norm. The obtained vectors result in a matrix, say $\mathbf{P}_{o}$. Any vector $\boldsymbol{e}_{i}$ can be decomposed in the form

$$
\boldsymbol{e}_{i}=\left(\boldsymbol{p}_{i}\right)_{o}+\boldsymbol{k}_{i}, \quad \text { where } \quad\left(\boldsymbol{p}_{i}\right)_{o} \in \mathcal{M}\left(\mathbf{A}^{\prime}\right) \quad \text { and } \quad \boldsymbol{k}_{i} \in \operatorname{Ker} \mathbf{A} .
$$

Note that $\operatorname{Ker} \mathbf{A}$ denotes as usually the set of all solutions of the homogeneous $\operatorname{system} \mathbf{A x}=\boldsymbol{0}$. The matrix consisting of the vectors $\boldsymbol{k}_{\boldsymbol{i}}$ will be denoted by $\mathbf{K}$. Let

$$
\boldsymbol{\vartheta}_{1}=\mathbf{P}_{0}^{\prime} \boldsymbol{\theta}, \boldsymbol{\vartheta}_{2}=\mathbf{K}^{\prime} \boldsymbol{\theta}
$$

Let us note that $\mathbf{P}_{o}^{\prime}=\mathbf{A}^{\prime}\left(\mathbf{A A}^{\prime}\right)^{-} \mathbf{A}$.
Lemma 3.1. $\mathrm{E}_{\theta}\left(\hat{\vartheta}_{2}\right)=\boldsymbol{0}$ for $\hat{\vartheta}_{2}=\mathbf{K}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{1(\mathbf{I}), \mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi$.
The Lemma follows if we use the definition of I-least square $g$-inverse.
Remark 3.1. The only possible projection operator $P_{M(A)}^{\mathbf{I}}$ projecting the columns of the matrix I onto the manifold $\mathcal{M}\left(\mathbf{A}^{\prime}\right)$ is the following one:

$$
P_{\mathcal{M}\left(\mathbf{A}^{\prime}\right)}^{\mathbf{I}}=\mathbf{A}^{\prime}\left(\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}
$$

Thus $\boldsymbol{\vartheta}_{1}=\mathbf{A}^{\prime}\left(\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A} \boldsymbol{\theta}$ and $\boldsymbol{\vartheta}_{2}=\left(\mathbf{I}-\mathbf{A}^{\prime}\left(\mathbf{A A}^{\prime}\right)^{-} \mathbf{A}\right) \boldsymbol{\theta}$.
Lemma 3.2. Let $\vartheta_{1}=\mathbf{A}^{\prime}\left(\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A} \theta$. Then the random vector $\hat{\vartheta}_{1}$ given by the relation

$$
\hat{\boldsymbol{\vartheta}}_{1}=\mathbf{A}^{\prime}\left(\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi
$$

has the following property
(i) $\mathrm{E}\left(\hat{\vartheta}_{1}\right)=\vartheta_{1}$
(ii) if $\tilde{\vartheta}_{1} \in \mathcal{M}\left(\mathbf{A}^{\prime}\right)$ such that $\mathrm{E}\left(\tilde{\vartheta}_{1}\right)=\vartheta_{1}$ then $\left\|\tilde{\vartheta}_{1}\right\|_{\Sigma_{\xi}}-\left\|\tilde{\vartheta}_{1}\right\|_{\Sigma_{\xi}} \geqslant 0$.

Theorem 3.1. Let $\xi$ be a gaussian vector with $\mathrm{E}_{\theta}(\xi)=\mathbf{A} \theta, \Sigma_{\xi}=\sigma^{2} \mathbf{H}$. Let $\sigma^{2}$ as well as $\mathbf{H}$ be known. Then the true value of the parameter $\theta$ lies in the set $\mathscr{L}$ with the probability $\operatorname{Prob}\left(\chi^{2}(r) \leqslant \mathrm{c}^{2}\right)$. Here $\mathscr{L}=\{\boldsymbol{x}+\boldsymbol{y}: \boldsymbol{x} \in \mathscr{K}, \boldsymbol{y} \in \operatorname{Ker} \mathbf{A}\}$, where

$$
\begin{aligned}
\mathscr{K}= & \left\{\boldsymbol{y}:\left(\boldsymbol{y}-\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi\right)^{\prime}\left[\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{P}_{o}\right]^{-} \times\right. \\
& \left.\times\left(\boldsymbol{y}-\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi\right) / \sigma^{2} \leqslant \mathrm{c}^{2}\right\} \cap \\
& \cap\left\{\mathcal{M}\left(\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{P}_{o}\right)+\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi\right\}
\end{aligned}
$$

and

$$
r=\mathbf{R}\left(\mathbf{H}\left(\mathbf{H}+\mathbf{A} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\right)
$$

Theorem 3.2. Let $\xi$ be a gaussian vector with $\mathrm{E}_{\theta}(\xi)=\mathbf{A} \theta, \Sigma_{\xi}=\sigma^{2} \mathrm{H}$. Let $\sigma^{2}$ be an unknown parameter and $\mathbf{H}$ be a known matrix, respectively. Then the true value of the parameter $\theta$ lies in the set

$$
\mathscr{W}=\{\boldsymbol{x}+\boldsymbol{y}: \boldsymbol{x} \in \tilde{\mathscr{K}}, \boldsymbol{y} \in \operatorname{Ker} \mathbf{A}\}
$$

with the probablity

$$
\operatorname{Prob}\left(\mathrm{F}(r, \mathrm{R}(\mathbf{H}, \mathbf{A})-\mathrm{R}(\mathbf{A})) \leqslant \mathrm{c}^{2}\right) .
$$

Here

$$
\begin{gathered}
\tilde{\mathscr{K}}=\left\{\boldsymbol{y}:-\mathcal{l}(\boldsymbol{y}) / \mathrm{B} \leqslant \mathrm{c}^{2}\right\} \cap\left\{\mathcal{M}\left(\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{P}_{o}\right)+\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi\right. \\
\mathcal{l}(\boldsymbol{y})=\left(\boldsymbol{y}-\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H}}^{-}\right]^{\prime} \xi\right)^{\prime}\left[\mathbf{P}_{o}^{\prime}\left(\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \mathbf{H}\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-} \mathbf{P}_{o}\right]^{-} \times \\
\times\left(\boldsymbol{y}-\mathbf{P}_{o}^{\prime}\left[\left(\mathbf{A}^{\prime}\right)_{\mathrm{m}(\mathbf{H})}^{-}\right]^{\prime} \xi\right) / r, \\
\cdot \mathbf{B}=\boldsymbol{v}^{\prime} \mathbf{H}^{-} \boldsymbol{v} /(\mathbf{R}(\mathbf{H}, \mathbf{A})-\mathbf{R}(\mathbf{A})), \quad r=\mathbf{R}\left(\mathbf{H}\left(\mathbf{H}+\mathbf{A}^{\prime} \mathbf{A}^{\prime}\right)^{-} \mathbf{A}\right) .
\end{gathered}
$$

The proofs of Theorems 3.1 and 3.2 follow from Section 2. It suffices to consider the confidence region for the projection $\vartheta_{1}$ of the parameter $\theta$ because of the fact that $\mathrm{E}\left(\hat{\boldsymbol{\vartheta}}_{2}\right)=0$.

It is easy to see that the sets $\mathscr{L}$, resp. $\mathscr{W}$, from the Theorems above consist of two parts. The first part $\mathscr{K}$ (resp. $\tilde{\mathscr{K}}$ ) is the set where lies the projection $\vartheta_{1}$ of $\theta$, which is an unbiassedly estimable parameter, with $\operatorname{Prob}\left(\chi^{2}(r) \leqslant \mathrm{c}^{2}\right)$ (resp. $\operatorname{Prob}(\mathrm{F}(r$, $\left.\mathbf{R}(\mathbf{H}, \mathbf{A})-\mathbf{R}(\mathbf{A})) \leqslant \mathrm{c}^{2}\right)$ ).

## ДОВЕРИТЕЛЬНАЯ ОБЛАСТЬ ВЕКТОРНОГО ПАРАМЕТРА

## Юлия Волауфова

## Резюме

В рамках регрессионной модели ( $\xi, \mathbf{A} \theta, \sigma^{2} \mathbf{H}$ ) решается проблема доверительной области как для несмещенно оцениваемой функции векторного параметра, так и для несмещенно неоцениваемого векторного параметра $\boldsymbol{\theta}$. Предполагается, что матрицы $\mathbf{H}$ и $\mathbf{A}$ известны, а $\boldsymbol{\sigma}^{2}$ может быть известный или неизвестный параметр.
