# One Erdős style inequality 

Tomáš J. Kepka, Petr C. Němec<br>Dedicated to the memory of Vèra Trnková

#### Abstract

One unusual inequality is examined.

Keywords: inequality
Classification: 11D75

In 1951, P. Erdős in [1] investigated the diophantine equation

$$
\begin{equation*}
\binom{n}{k}=x^{l}, \quad k \geq 2, n \geq 2 k, x>1, l>1 \tag{1}
\end{equation*}
$$

and he showed that this equation has no solution for $k>3$ (there are infinitely many solutions if $k=l=2$, and for $k=3, l=2$, equation (1) has only one solution $n=50, x=140$ ). The remaining cases $k=2,3$ and $l>2$ were settled by K. Győry in [2]. The proof in [1] is making use of some quite unusual inequalities and one of them, namely the inequality $(h-g)^{3}>h$, is carefully examined and generalized in this ultrashort note. Needless to say that our approach is fully calculus-free.

First of all, let $a, b, c$ be positive integers such that $a<c$ and $a c=b^{2}$. Then $a<b<c$ and the well-known relation of arithmetic and geometric means yields $a+c>2 b$. Put $m=c-b, n=b-a$ and $p=m-n=a+c-2 b$. Then $m, n, p \geq 1$, $m \geq n+1$ and $b m=b(c-b)=b c-b^{2}=b c-a c=(b-a) c=n c$. Hence

$$
\begin{equation*}
b p=b(m-n)=b m-b n=n c-b n=n m . \tag{2}
\end{equation*}
$$

Since $m \geq n+1$ and $p \geq 1$, (2) implies $m^{2} \geq(n+1) m=n m+m=b p+m \geq b+m$, and consequently $m^{2}-m \geq b$. From this,

$$
\begin{equation*}
m^{2}-(m+n)=m^{2}-m-n \geq b-n=a \tag{3}
\end{equation*}
$$

As $m+n=c-a$, we have $m^{2}-(m+n)=(c-b)^{2}-c+a$. By $(3),(c-b)^{2} \geq c$, and hence

$$
\begin{equation*}
(c-a)^{2}>c \tag{4}
\end{equation*}
$$

Now, let $g, h$ be positive integers such that $g \leq a, c \leq h$ and put $\delta=h-c$. Using (4), we obtain $(h-g)^{2} \geq(h-a)^{2}=(c-a+\delta)^{2} \geq(c-a)^{2}+\delta>c+\delta=h$.

Let $a, b, c, d, e, f, g, h, t, \alpha, \beta, \gamma$ be positive integers satisfying $a \neq b \neq c \neq a$, $g \leq \min (a, b, c), \max (a, b, c) \leq h, 5 h \leq 6 g, t \geq 3, \beta^{2}=\alpha \gamma, a=\alpha d^{t}, b=\beta e^{t}$, $c=\gamma f^{t}$. We aim to show that $(h-g)^{3}>h$.

The case $b^{2}=a c$ is settled down in the above-mentioned part, where we got $(h-g)^{2}>h$. In view of this, we can restrict ourselves to the case $b^{2}>a c$ (the other case, $a c>b^{2}$, being quite analogous). We can assume $a<c$ as well. Then, of course, $g \leq a<b \leq h, g \leq a<c \leq h$ and

$$
\begin{equation*}
g^{2}<a c \tag{5}
\end{equation*}
$$

Furthermore, $b^{2}-a c=\beta^{2} e^{2 t}-\alpha \gamma(d f)^{t}=\beta^{2}\left(e^{2 t}-(d f)^{t}\right)>0$, hence $e^{2} \geq d f+1$ and $b^{2}-a c \geq \beta^{2}\left((d f+1)^{t}-(d f)^{t}\right) \geq \beta^{2} t(d f)^{t-1}$. Thus

$$
\begin{equation*}
d f\left(b^{2}-a c\right) \geq \beta^{2} t(d f)^{t}=t \alpha d^{t} \gamma f^{t}=t a c \tag{6}
\end{equation*}
$$

Now, $2(h-g) h=(h-g)^{2}+h^{2}-g^{2}>(h-g)^{2}+b^{2}-a c$ by (5). Using (6) and (5), we see that $2(h-g) h d f>(h-g)^{2} d f+\left(b^{2}-a c\right) d f \geq(h-g)^{2} d f+t a c>$ $(h-g)^{2} d f+t g^{2}>t g^{2}$. Since $t \geq 3$ and $5 h \leq 6 g$, we have $t g^{2} \geq 3(h-(h-g))^{2}=$ $3 h^{2}-6 h(h-g)+3(h-g)^{2}=2 h^{2}+h(h-6(h-g))+3(h-g) g^{2}>2 h^{2}$, and therefore

$$
\begin{equation*}
(h-g) d f>h \tag{7}
\end{equation*}
$$

Let $s$ be an integer such that $4 \leq s \leq t+2$. We have $(h-g)^{s-2} h^{s}>$ $(h-g)^{s-2} h^{s-2} a c=\beta^{2}(h-g)^{s-2} h^{s-2} d^{t} f^{t} \geq \beta^{2}(h-g)^{s-2} h^{s-2} d^{s-2} f^{s-2}=$ $\beta^{2}((h-g) d f)^{s-2} h^{s-2}>\beta^{2} h^{2 s-4}$ by (7), and hence

$$
(h-g)^{s-2}>\beta^{2} h^{s-4} \geq h^{s-4}
$$

For $s=t+2$ we get $(h-g)^{t}>h^{t-2}$. For $s=5$, we get $(h-g)^{3}>h$. If $\bar{g}=\min (a, b, c)$ and $\bar{h}=\max (a, b, c)$ then $5 \bar{h} \leq 6 \bar{g}$ and $(\bar{h}-\bar{g})^{3}>\bar{h}$.

We have shown that the inequality $(h-g)^{3}>h$ holds if $5 h \leq 6 g$ and some unusual additional conditions are satisfied. On the other hand, $5 \cdot 18<6 \cdot 16$, but $(18-16)^{3}<18$. If $5 h>6 g$ and $h \geq 15$ then $6^{3}(h-g)^{3}>h^{3} \geq 6^{3} h$ and the inequality holds.

Now, let us have a look at the inequality $(h-g)^{3}>h$ from another point of view. Let $H, g, h, \Delta$ be positive integers such that $H \geq 3$ and $\Delta \geq 2$. Put $G_{H}=H-1-[\sqrt[3]{H}]$ (here $[\alpha]$ denotes the integer part of $\alpha$ ). Then $H-G_{H} \geq 2$, $\left(H-G_{H}\right)^{3}>H$ and $(H-g)^{3} \leq H$ for $g>G_{H}$. If $g \leq G, h \geq H$ and $\delta=h-H$ then $(h-g)^{3} \geq\left(h-G_{H}\right)^{3}=\left(H-G_{H}+d\right)^{3} \geq\left(H-G_{H}\right)^{3}+\delta>H+\delta=h$.

Let $(\Delta-1)^{3} \leq H \leq \Delta^{3}-1$. Then $G_{H}=H-\Delta$ and, moreover, $5 H \leq 6 G_{H}$ if and only if $6 \Delta \leq H$. Since $6 \Delta<(D-1)^{3}$ for $\Delta \geq 4$, we see that $5 H \leq 6 G_{H}$ if and only if $H \geq 18$. Finally, $g$ such that $g \leq H-2,(H-g)^{3} \leq H$ exists if and only if $H \geq 8$. If $g$ is so then $5 H>6 g$ for $H \leq 11$ and $5 H \leq 6 g$ otherwise.

Acknowledgement. The authors would like to express their thanks to the anonymous referee for her/his fruitful comments which helped to improve the readability of this note.
