Seventh Winter School on Abstract Analysis 1979
Some extreme contractions on $\ell_{\mathrm{p}}$-spaces R. Gząślewicz

An operator $T \in \mathscr{L}\left(\ell_{\mathrm{p}}(A), \ell_{\mathrm{p}}(\mathrm{B})\right)$ is extreme contraction if it is an extreme point of unit ball (A,B - index sets, $\boldsymbol{l}_{\mathrm{p}}(\mathrm{A})$ -- Banach space (over $\mathbb{R}$ or $C$ ) of all p-summable functions on $A$ ). Let $I \leq p \leq \infty$.

For $p=\infty$ we can characterize all extreme contractions as the lattice homomorphisms taking 1 into 1 multiplied by functions of absolute value 1 [M.Shaver, Israel J. Math. 12 (1972), C.Kim, Math. Zeitsch. 151 (1976), A.Iwanik, Colloq.Math. 40] •

For $p=1$ and real $l_{1}$-space extr. contr. can be characterized (by duality) [Iwanik, Kim] .

For $p=2$ and field $C$ the set of extr. contr. coincides with the set of all isometries and coisometries [Kadison, Ann. Math. 54 (1951)].

For $\alpha \in A$ we denote by ${ }^{\circ} e_{\alpha}$ the element of $\ell_{p}(A)$ defined by $e_{\alpha}(\gamma)=\delta_{\alpha \gamma}, \gamma \in A$. The index family $\cdot\left(e_{\alpha}\right)_{\alpha \in A}$ forms the canonical basis of E .

To every operator $T \in \mathscr{L}\left(l_{p}(A), l_{p}(B)\right)$ there corresponds a unique matrix with scalar entries $\left(t_{\beta \alpha}\right), \alpha \in A, \beta \in B$ s.t. the $\alpha$-th column represents $T_{e \alpha}$ in the canonical basis (e $\beta$ ) of $l_{p}(B)$.

According to the behaviour of $T$, we will partition the index sets $A, B$ into disjoint subsets $A_{i}, B_{i}(i=0,1,2,3,4)$. Let $A_{0}=\left\{\alpha \in A,{ }^{t}{ }_{\beta \alpha}=0\right.$ for all $\left.\beta \in B\right\}, B_{0}=\{\beta \in B$,
$t_{\beta \alpha}=0$ for all $\left.\alpha \in \perp\right\}$. Next let $C$ be the set of all alements $\alpha \in A$ such that:
(1) there exists a $\beta \in B$ with $t_{\beta \lambda} \neq 0$ and
(2) if $t_{\beta \alpha}=0$ for some $\beta \in B$, then $t_{\beta \gamma}=0$ for all $\gamma \neq \alpha$.
Now we define $A_{1}$ to be the set of all elements $\alpha \in A$ set. $t_{\beta \alpha} \neq 0$ for only one $\beta \in B$ and we put $A_{2}=C \backslash A_{1}$. Let $A_{3}$ be the set of all $\alpha \in A \backslash A_{1}$ such that:
(i) there exists exactly one $\beta \in B$ with $t_{\beta x} \neq 0$ and
(ii) $t_{\beta \gamma} \neq 0 \Rightarrow{ }_{3}^{t} \delta_{\gamma}=0$ for all $\delta \neq \beta$. Finally we put

$$
A_{4}=A \backslash\left(\bigcup_{i=0} A_{i}\right)
$$

For $i=1,2,3,4$ let $B_{i}=\left\{\beta \in B, t_{\beta a} \neq 0\right.$ for some $\left.\alpha \in A_{i}\right\}$ (Fig. 1).

Theorem 1. Let $1<p<\infty, p \neq 2, T \in \mathscr{L}\left(\ell_{p}(A), l_{p}(B)\right)$ and let $A_{4}=\varnothing,\|T\| \leq 1$. Then $T$ is an extreme contraction ff the following two conditions are satisfied.
(a) $\left\|T e_{\alpha}\right\|=1$ for $\alpha \in A$ and $\left\|T e_{\beta}\right\|=1$ for $\beta \in B$, (b) $A_{0}=\varnothing$ or $A_{2}=B_{0}=\varnothing$ in the case of $I<p<2$ and

$$
B_{0}=\varnothing \text { or } B_{3}=A_{0}=\varnothing \text { in the case of } 2<p<\infty
$$

Corollary. For $p \neq 2(1<p<\infty)$ the set of all extreme contfractions on the $l_{\mathrm{p}}$-space ( $\operatorname{dim} \geq 2$ ) is not closed.

Let $X$ denote the two-dim $l_{\mathrm{p}}$-space.
Theorem 2. Let $1<p<\infty, \mathrm{p} \neq 2$ and $T \in \mathscr{L}(\mathrm{X}, \mathrm{X}) ;\|\mathrm{T}\|=1$. Then $T$ is an extreme contraction ff either $T$ attains its norm in two linearly independent vectors in $X$ or $T$ is of the form

$$
\begin{array}{ll}
I^{0} T=X \otimes e_{i} & \text { in the case of } 1<p<2 \\
2^{0} T=e_{i} \otimes y & \text { in the case of } 2<p<\infty
\end{array}
$$

with $x, y \neq e_{j}(i, j=1,2),\|x\|=\|y\|=1$, ie.
$x \otimes y: x \rightarrow x, \quad(x \otimes y)(z)=\langle z, x\rangle y$.

$z \in X$
