## PARACOMPACTNESS IN BOX PRODUCTS

```
scott w. williams
```

For fifteen years there has been an active search for classes of spaces for which paracompactness occurs in box products (see surveys [3] and [13]). However, very little has been accomplished in the case of uncountably many factors - the case considered here.

In [2], van Douwen proved that for a very special class of paracompact $P$ spaces, the $\omega_{\mu}$-metrizable spaces, box products are paracompact if there are not too many factors. Prior to the present paper, this was the only "positive" result using nothing other than ZFC. Our first theorem is of a similar nature, but new even for the countable factors case.

```
1.3). If \(X_{\alpha}\) is a paracompact scattered \(P\)-space for each \(\alpha \in \omega_{1}\), then \(<\omega_{1}-\square_{\alpha} X_{\alpha}\) is paracompact.
```

Miller extended part of Kunen's nabla lemma from box products of countably many spaces to the countable support box product, < $\omega_{1}-\square_{\alpha} X_{\alpha}$, of $\omega_{1}$ many spaces [10]. In our section 2 we present a similar extension for the other part of the nabla lemma. This extension is applied in section 3 to prove
3.1). [CH] If $X_{\alpha}$ is a paracompact locally compact scattered space for each $\alpha \in \omega_{1}$, then $<\omega_{1}-\square_{\alpha} X_{\alpha}$ is paracompact.

Our section 4 , adds to the list of non-paracompact box products of compact spaces with an example whose proof is quite different trom all the rest. We show
4.3). The box product of countably many compact orderable spaces need not be c-Lindelof.

In the final section we remark on recent efforts to understand the full box product topology of uncountably many compact first countable spaces.

This paper is in final form and no version of it will be submitted for publication elsewhere.

PRELIMINARIES: All spaces are regular Hausdorff. All cardinals are regular von Neumann ordinals. $\underline{c}=2^{\omega}$. $C H$ denotes the continuum hypothesis and MA denotes Martin's axiom. If $x$ is a cardinal and if $X$ is a set, then $[X]^{<\mathcal{K}}$ denotes the set of all subsets $Y$ of $X$ whose cardinality $|Y|$ is less than $\mathcal{X}$.

Suppose that $x$ is a cardinal, and for each $\alpha \in x X_{\alpha}$ is a space. An open box in $\Pi_{\alpha} X_{\alpha}$ is a set of the form $B=\Pi_{\alpha} B_{\alpha}$ where $B_{\alpha}$ is an open subset of $X_{\alpha}$ for each $\alpha$. The support of the open box $B$ is the set $\operatorname{spt}(B)=\left\{\alpha \in u: B_{\alpha} \neq X_{\alpha}\right\}$. If $\lambda$ is also a cardinal, then $<\lambda-\square_{\alpha} X_{\alpha}$ denotes the set $\Pi_{\alpha} X_{\alpha}$ with the
 When $x<\lambda$, we use $\square_{\alpha} X_{\alpha}$ instead of $<\lambda-\square_{\alpha} X_{\alpha}$ and call it the full box product.
§1. A paracompact box product in ZFC

Recall that a space is called scattered provided each of its non-empty subspaces contains an isolated point. For a useful characterization of "scattered", recall the Cantor-Bendixen decomposition of a space $X$ :

Let $X^{\prime}$ consist of the set of non-isolated points of $X$, and let $X^{(0)}=X$. Define, inductively, for each non-zero ordinal $\alpha, X^{(\alpha)}=\cap_{\beta<\alpha}\left(X^{(\beta)}\right)^{\prime}$. It is known that $X$ is scattered iff $H^{\prime} X^{(\alpha)}=\phi$.
1.1. DEFINITION. Suppose that $X$ is a scattered space and $A \subseteq X$. Define the rank of $A$ by

$$
\operatorname{rk}(A)=\inf \left\{\alpha: A \cap X^{(\alpha)}=\phi\right\} .
$$

Define the top of $A$ by

$$
t_{p}(A)=\left\{\begin{array}{cl}
A \cap X^{(\alpha)}, & \text { if } r k(A)=\alpha+1 \\
\phi, & \text { if } \operatorname{rk}(A) \text { is a limit ordinal. }
\end{array}\right.
$$

We will say $A$ is capped whenever $\left|t_{p}(A)\right|=1$.
1.2. LEMMA [12]. Suppose that $X$ is a paracompact scattered space. Then each open covering of $\cdot X$ is refined by a pairwise-disjoint open capped refinement. //

The following conventions, for a family $u$ of sets, are in use: For a set $X, u \mid X=\{U \cap X: U \in L\}$. A family $v$ of sets refines $u$ provided $U V=U U$ and, for each $V \in U$ there is a $U_{V} \in u$ with $V \subseteq U_{V}$.

Recall that a P-space is a space in which each $G_{\delta}$-set is open.
1.3. THEOREM. Suppose that for each $\alpha \in \omega_{1}, X_{\alpha}$ is a paracompact scattered P-space. Then $<\omega-\square_{\alpha} X_{\alpha}$ is paracompact.

PROOF. We may assume each $X_{\alpha}$ is infinite, and we let $\square$ denote $<\omega_{1}-\square_{\alpha} X_{\alpha}$. According to 1.2 , $\square$ possesses a base $\mathbb{B}$ consisting of countable boxes $B$ such that $B_{\alpha}$ is a clopen capped set of $X_{\alpha}$ for each $\alpha \in \operatorname{spt}(B)$. Obviously, we may assume, without loss of generality, that $\operatorname{spt}(B) \in \omega_{1}$ for each $B \in \mathbb{B}$, define

$$
T_{p}(B)=\left\{x \in \Pi_{\alpha} X_{\alpha}:\left\{x_{\alpha}\right\}=t_{p}\left(B_{\alpha}\right) \forall \alpha \in \operatorname{spt}(B)\right\} .
$$

Suppose that $\mathcal{C} \subseteq B$ covers $\square$. We will show $\mathcal{G}$ is refined by a pairwise disjoint subset of $\mathbb{B}$. Given a family $W \subseteq \mathbb{B}$ define

$$
\begin{aligned}
& w^{\#}=\left\{W \in W: \operatorname{GG} \in \mathcal{G}, \operatorname{spt}(G) \leq \operatorname{spt}(W) \text { and } T_{p}(W) \subseteq G\right\}, \text { and } \\
& w^{*}=\{W \in W: \text { gG } \in \mathcal{G}, W \subseteq G\} .
\end{aligned}
$$

According to $1.2 X_{0}$ is covered by a pairwise-disjoint open capped family P. Set

$$
u(0)=\left\{B \in B: B_{0} \in P \text { and } \operatorname{spt}(B)=0\right\} .
$$

Obviously $u(0)$ is a pairwise-disjoint open covering of $\square$. We now define, inductively for each non-zero ordinal $\nu \leq \omega_{1}$, a family $u(v)$ subject to the restrictions (1) through (8) below:
(1). $U(v)$ is a pairwise-disjoint subset of $B$ covering $\square$.
(2). if $v \in u(v)$, then $\operatorname{spt}(v) \leq \sup \{\mu+1: \mu<\nu\}$.
(3). if $v$ is a limit ordinal and if $v \in u(v)$, then $V=\cap\{U: \nexists \mu<\nu, U \in u(\mu), V \subseteq U\}$.
For $\quad \nu=\mu+1$,
(4). $u(v)$ refines $u(\mu)$.
(5). $u(v) \cap U(u)=u(v)^{*}$.
(6). if $U \in u(u)^{\#}$, then $\operatorname{spt}(V)=\operatorname{spt}(U) \forall V \in u(v) \mid U$.
(7). if $U \in u(u)^{\#}$, then $\mathbb{G V} \in u(v)^{*}, T_{p}(U) \subseteq V$.
(8). if $u \in u(u) \backslash u(u)^{\#}$, then $\operatorname{spt}(v)=v+1 \forall v \in u(v) \mid u$.

Suppose $\xi \leq \omega_{1}$ and $\forall \nu<\xi$ we have constructed $L(\nu)$ subject to the conditions (1)-(8). We define $\mathcal{L}(\xi)$.

Case 1. $\xi$ is a successor ordinal, say $\xi=\mu+1$. In order to satisfy (1) and (4), we define for each $U \in U(\mu)$, a pairwise-disjoint family $\mathcal{V}_{U} \subseteq \mathbb{B}$ covering $U$, and require $U(\xi)\left|U=U_{U}\right| U$. This is clear when $U \in U(\mu)^{*}$ for we just let $U_{U}=\{U\}$. So (5) will be fulfilled.

If $U \in U(\mu)^{\sharp} \mid u(\mu)^{*}$, choose one $G \in G$ such that $\operatorname{spt}(G) \leq \operatorname{spt}(U)$ and $G \cap T_{p}(U) \neq \phi$. For each $\alpha \in \operatorname{spt}(U)$, we apply 1.2 to find a pairwise-disjoint clopen capped refinement $\mathcal{F}_{\alpha}$ of $\left\{U_{\alpha} \cap G_{\alpha}, U_{\alpha} \backslash G_{\alpha}\right\}$. Now let

$$
U_{U}=\left\{V \in B: V_{\alpha} \in \mathfrak{F}_{\alpha} \text { if } \alpha \in \operatorname{spt}(U) \text { and } \operatorname{spt}(V)=\operatorname{spt}(U)\right\}
$$

In order to see that (6) and (7) hold, suppose $y \in T_{p}(U)$. Then for each $\alpha \in \operatorname{spt}(U) \quad \forall F_{\alpha} \in \mathcal{F}_{\alpha}$ such that $y_{\alpha} \in F_{\alpha} \subseteq U_{\alpha} \cap G_{\alpha}$.

If $U \in U(\mu) \backslash U(\mu)^{\#}$, apply 1.2 again to find a pairwise-disjoint open capped covering $P_{\alpha}$ of $X_{\alpha}$ for each $\alpha$ satisfying $\operatorname{spt}(U) \leq \alpha \leq \xi$. Define

$$
v_{U}=\left\{V \in B: v_{\alpha} \in P_{\alpha} \text { if } \operatorname{spt}(U) \leq \alpha \leq \xi, \quad \text { and } \quad V_{\alpha}=U_{\alpha} \text { otherwise }\right\}
$$

It is easy to see (1)-(8) are satisfied.

Case 2. $\xi$ is a limit ordinal. From (1), (3), and (4) we observe that if $v=\left\{\cap M: \cap M \neq \phi\right.$ and $m$ is a maximal chain of $\left.\left(U_{v<\xi} u(v), \subseteq\right)\right\}$, then $V=\cap\{U: \nexists v<\xi, U \in U(\nu), V \subseteq U\}$ for each $V \in U$. (1), (3), and (4) also imply $l$ is a pairwise-disjoint cover of $\square$. If $\checkmark \subseteq \mathbb{B}$, then we are done for then $u(\xi)=v$ easily satisfies (1)-(8). So we show $\cup \subseteq \mathbb{B}$.

Suppose that $V \in u$, and for each $v<\xi$ we have $U(v) \in U(v)$ so that $V=\cap_{V<\xi} U(v) \in U$. Then we have the inequality
(9). $\quad v=\cap_{v<\xi} \Pi_{\alpha} U(v)_{\alpha}=\Pi_{\alpha}\left(\cap_{v<\xi} U(v)_{\alpha}\right)$.

For each $\alpha \in \omega_{1}$, put $V_{\alpha}=\cap_{V<\xi} U(v)_{\alpha}$. Then $V \in B$ if $|\operatorname{spt}(V)|<\omega_{1}$ and if $V_{\alpha}$ is a clopen capped set of $X_{\alpha}$ for each $\alpha \in \operatorname{spt}\left(V_{\alpha}\right)$.

Fix $\alpha \in \omega_{1}$. Then (2) and (3) show $U(\nu)_{\alpha} \subseteq U(\mu)_{\alpha}$ whenever $\mu<\nu<\xi$. So $\mu<\nu$ implies $r k(U(\nu)) \leq r k(U(\mu))$. Since every decreasing sequence of ordinals is finjte, there is a $v_{\alpha}<\xi$ such that

$$
\operatorname{rk}\left(U(v)_{\alpha}\right)=\operatorname{rk}\left(U\left(v_{\alpha}\right)_{\alpha}\right) \forall v, v_{\alpha}<v<\xi .
$$

In particular, we have

$$
\text { (10). } \quad \operatorname{rk}\left(V_{\alpha}\right)=\operatorname{rk}\left(U\left(\nu_{\alpha}\right)_{\alpha}\right)
$$

So if $V_{\alpha} \neq X_{\alpha}$, then $V_{\alpha}$ is a closed capped set of $X_{\alpha}$. As $X_{\alpha}$ is a P-space,
we see that (9) implies $V_{\alpha}$ is open if
(11). $\{U(\nu): \nu<\xi\}$ is countable.

Let $\alpha$ vary in $\omega_{1}$. Note that (2) applied to the $U(v)$ shows $\operatorname{spt}(V)$ is an ordinal and $\operatorname{spt}(V) \leq \xi$. Thus, $\xi<\omega_{1}$ implies (11) holds and hence $V \in \mathbb{B}$. So we assume $\xi=\omega_{1}$.

Choose an $x \in \square$ such that $\left\{x_{\alpha}\right\}=t_{p}\left(V_{\alpha}\right) \forall \alpha \in \operatorname{spt}(V)$. Then there is a $G \in \mathcal{G}$ such that $x \in G$. Let

$$
\lambda=\left(\sup \left\{v_{\alpha}: \alpha \in \operatorname{spt}(G)\right\}\right)+1
$$

Then (10) implies $\left\{x_{\alpha}\right\}=t_{p}\left(U(\lambda)_{\alpha}\right)$ whenever $\alpha<\operatorname{spt}(G)$. So $U(\lambda) \in u(\lambda)^{\#}$. From (6), $\operatorname{spt}(U(\lambda+1))=\operatorname{spt}(U(\lambda))$. Since $V \subseteq U(\lambda+1)$, we use (10) to show $t_{p}\left(U(\lambda+1)_{\alpha}\right)=\{x\} \forall \alpha \in \operatorname{spt}(G)$. So (7) implies $U(\lambda+1) \in u(\lambda+1)^{*}$. Therefore, $U(\nu)=U(\lambda+1)$ whenever $\lambda<\nu<\omega_{1}$. Thus (11) holds for $\xi=\omega_{1}$ This completes our construction of $u(v) \forall v \leq \omega_{1}$.

According to (3) and (5), (11) implies that for each $U \in U\left(\omega_{1}\right)$ there is a. $v \in \omega_{1}$ such that $U \in U(v)^{*}$. From (1), $U\left(\omega_{1}\right)$ is the desired refinement of G . //

The theorem 1.3 is new even for the countably many factors case that we presented at the 1983 Annual Winter Meetings of the American Mathematical Society. Independently, Rudin and Watson proved that the Tychonov product of countably many paracompact scattered spaces in paracompact [11]. The proof, given above, of 1.3 combines elements of both our earlier result and the theorem in [11].

Question 1: Suppose that $X_{\alpha}$ is a paracompact scattered space for each $\alpha \in \omega_{1}$. Is $<\omega_{1}-\square_{\alpha} X_{\alpha} \quad$ paracompact?

Without the P-space assumption, or assuming locally compact factors (see section 3), nothing (even consistently) is known about Question 1.
§2. The countable support nabla 1emma.

A most useful tool in studying box products with locally compact factors is the so-called nabla product $\nabla$, which is not really a product.
2.1. DEFINITION. Suppose that $x$ is an infinite cardinal, $\theta$ is an ideal on $x$, and $X_{\alpha}$ is a set for each $\alpha \in \mu$. On $\Pi_{\alpha} X_{\alpha}$ define a relation $\sim_{g}$ by

$$
x \sim_{\Omega} y \text { iff }\{\alpha \in x: x(\alpha) \neq y(\alpha)\} \in \mathscr{d}
$$

Let $\nabla_{\mathscr{\ell}, \alpha} X_{\alpha}$ denote the set of equivalence classes of $\sim_{\mathscr{g}}$, and $q: \pi_{\alpha} X_{\alpha}+\nabla_{\mathscr{g}, \alpha} X_{\alpha}$
the quotient map. If $\Pi_{\alpha} \dot{X}_{\alpha}$ has a topology, then we give $\nabla_{\varrho, \alpha} X_{\alpha}$ the quotient topology. For most of this paper $\ell$ will consist of all finite subsets $u f n$ and $\Pi_{\alpha} X_{\alpha}$ will be the space $<\omega_{1}-\square_{\alpha} X_{\alpha}$. In this case $\nabla_{\alpha} X_{\alpha}$ shall denote $\nabla_{\ell, \alpha} X_{\alpha}$.

### 2.2. LEMMA [8]. $\nabla_{\alpha} X_{\alpha}$ is a P-space and $q$ is an open continuous map. //

2.3. LEMMA. Suppose that. $x$ is a cardinal, and for each $\alpha \in x X_{\alpha}$ is a $\sigma$ - compact locally compact space. Suppose $x \in<\omega_{1}-\square_{\alpha} X_{\alpha}$ and $\mathcal{G}$ is an open cover of $q^{-1} q_{(x)}$. Then there is an open box $U$, with countable supporc, neighborhood of $x$ such that $q^{-1} q(U)$ is covered by a countable subfamily of G.

PROOF. Let $\square$ denote $<\omega_{1}-\square_{\alpha} \leqslant X_{\alpha}$. As each $X_{\alpha}$ is a $\sigma$-compact and locally compact, we may write $X_{\alpha}=U_{n} \in \omega$ $X(\alpha, n)$, where $X(\alpha, n)$ is open in $X_{\alpha}$ and $X(\alpha, n)^{-}$is a compact subset of $X(\alpha, n+1)$ for each $n \in \omega$. Let $F \in{ }_{\omega}{ }_{\omega}$ be such that $x_{\alpha} \in X(\alpha, f(\alpha)) \forall \alpha \in X$. Let $B$ be the set of all open boxes $B=\Pi_{\alpha} B_{\alpha} \quad$ such that $|\operatorname{spt}(B)| \leq \omega$. Without loss of generality, we may assume $G \subseteq B$.

There are $G(0) \in \mathcal{G}$ and $B(0) \in \mathbb{B}$ such that for each $\alpha \in \operatorname{spt}(G(0))$,

$$
x_{\alpha} \in B(0)_{\alpha} \subseteq G(0)_{\alpha} \cap X(\alpha, f(\alpha))
$$

Put $S(0)=\phi, \mathcal{G}(0)=\{G(0)\}$, and let $\{\beta(0,1): i \in \omega\}$ be an indexing of spt( $B(0)$ ). We construct, inductively, for each positive $n \in \omega$, a finite family $\mathcal{C}(n) \subseteq \mathcal{C}$, a neighborhood $B(n) \in \mathbb{B}$ of $x$, an indexing $\{\beta(n, 1): 1 \in \omega\}$ of $\operatorname{spt}(B(n))$, and a finite set $S(n) \subseteq \mu$, all subject to the restrictions (1), (2), and (3) below:
(1). $x \in B(n) \subseteq B(n-1)$.
(2). $S(n)=\{\beta(m, i): m, i<n\}$.
(3). $\quad\left(\Pi_{\alpha \in S(n)} X(\alpha, f(\alpha)+n)\right) \times\left(\Pi_{\alpha \in x \backslash S(n)} B(n){ }_{\alpha}\right) \subseteq U G(n)$.

Given the construction $\forall n<k \in \omega$. We construct $\mathcal{G}(k), B(k)$, the set $\{\beta(k, i): i \in \omega\}$, and $S(k)$ as follows:

Put $S(k)=\{\beta(m, 1): m, i<k\}$. Since
is a compact subset of $\square$, it is covered by a finite family $\mathcal{G}(k) \subseteq \mathcal{G}$. Let $x \in H \in G(k)$ and define $B(k)$ by

$$
B(k)_{\alpha}=B(k-1)_{\alpha} \cap\left\{\begin{array}{ll}
H_{\alpha}, & \text { if } \alpha \in S(k) \\
n\left\{G_{\alpha}:\right. & G \in \mathbb{G}(k)\},
\end{array}\right] \quad \alpha \in x \backslash S(k) .
$$

Arbitrarily index $\operatorname{spt}(B(k))$ by $\{\beta(k, i): i \in \omega\}$. It is easy to see that ( 1 ), (2), and (3) hold, so we consider our construction complete for each $n \in \omega$.

Let $S=U_{n \in \ldots} S(n)$. Derine $U \in B$ by

$$
U_{\alpha}=\left\{\begin{array}{l}
B(n)_{\alpha}, \text { if } n \text { is the first integer such that } \alpha \in S(n) \\
X_{\alpha}, \text { if } \alpha \notin S
\end{array}\right.
$$

Then $J \in B$, and $\operatorname{spt}(U) \subseteq S$. Obviously, (1) implies $x \in U$.
To complete our proof, we show that for each finite set $\mathrm{A} \subseteq u$,
(4). $\quad\left(\pi_{\alpha} \in A^{X}{ }_{\alpha}\right) \times\left(\pi_{\alpha} \in x \backslash A^{U}{ }_{\alpha}\right) \subseteq\{G: \mathbb{Z}, G \in \mathbb{G}(n)\}$.

So suppose $A$ is a finite subset of $x$ and $y \in\left(\pi_{\alpha \in A^{\prime}}\right) \times\left(\pi_{\alpha \in x \backslash A} U_{\alpha}\right)$.
(5). $A \cap \operatorname{spt}(U) \subseteq S(k)$, and
(6). $y_{\alpha} \in X(\alpha, k) \forall \alpha \in A$
are true. We claim
(7). $y \in\left(\pi_{\alpha \in S(k)} X(\alpha, f(\alpha)+k)\right) \times\left(\pi_{\left.\left.\alpha \in x \backslash S(k)^{B(k)}\right)_{\alpha}\right)}\right.$
is also true. In fact, if we apply (3) to (7), we see that. $y \in \cup \mathcal{G}(k)$, and, as $y$ is arbitrary, this proves (4). In order to prove (7) we consider three cases.

Case 1. $\alpha \notin S$ : From (2), $\operatorname{spt}(B(k)) \subseteq S$. Hence, $y_{\alpha} \in X_{\alpha}={ }^{\prime} B(k)_{\alpha}$.
Case 2. $\alpha \in S \backslash S(k)$ : From (5), $\alpha \notin U_{\alpha}$. Find the first $n$ such that $\alpha \in S(n)$. Then $U_{\alpha}=B(n)_{\alpha}$. Since $\alpha \in S(n) \backslash S(k)$, (2) implies $k<n$. From (1), $y_{\alpha} \in B(n)_{\alpha} \subseteq B(k)_{\alpha}$.

Case 3. $\alpha \in \mathrm{S}(\mathrm{k})$ : From (6), $\mathrm{y}_{\alpha} \in \mathrm{X}(\alpha, \mathrm{k}) \subseteq \mathrm{X}(\alpha, \mathrm{f}(\alpha)+\mathrm{k})$.//
The following was established for compact factors by Kunen [5] with $x=\omega$ and Miller [9] with $x=\omega_{1}$, and for $\sigma$-compact locally compact factors by van Douwen [3] with $x=\omega$.
2.4. COROLLARY. Suppose that $X_{\alpha}$ is a $\sigma$-compact locally compact space for each $\alpha \in \mu$. Then (1). $q:<\omega_{1}-\nabla_{\alpha} X_{\alpha} \rightarrow \nabla_{\alpha} X_{\alpha}$ is a closed map, and
(2). $\mathrm{q}^{-1} \mathrm{q}(\mathrm{x})$ is Lindelof for each $\mathrm{x} \in \Pi_{\alpha} \mathrm{X}_{\alpha}$.

Proof: (2) is obvious. For (1) use the standard characterization [4] of closed maps: for each $x$ and each neighborhood $G$ of $q^{-1} q(x)$, there is a neighborhood $V$ of $q(x)$ such that $q^{-1}(V) \subseteq G$. In 2.3 take $G=\{G\}$ and $V=q(U)$.//
2.5. THE NABLA LEMMA. Suppose that $Y_{\alpha}$ is a paracompact locally compact space for each $\alpha \in \omega_{1}$. Then the following are equivalent:
(1). $<\omega_{1}-\square_{\alpha} Y_{\alpha}$ is paracompact.
(2). $<\omega_{1}-\square_{\alpha} X_{\alpha}$ is paracompact whenever $X_{\alpha}$ is a closed $\sigma$-compact locally compact subspace of $Y_{\alpha}$ for each $\alpha \in \omega_{1}$.
(3). $\nabla_{\alpha} X_{\alpha}$ is paracompact whenever $X_{\alpha}$ is a closed $\sigma$-compact locally compact subspace of $Y_{\alpha}$ for each $\alpha \in \omega_{1}$.

PROOF. (1) $\Rightarrow$ (2): This is clear since $<\omega_{1}-\square_{\alpha} X_{\alpha}$ is homeomorphic to the closed subset $\pi_{\alpha} X_{\alpha}$ of $<\omega_{1}-\square_{\alpha} Y_{\alpha}$.
(2) $\Leftrightarrow$ (3): This is an immediate consequence of 2.4 and E. Michael's theorem [8, Corollary 1] on image and pre-image preservation of paracompactness.
$(2) \Rightarrow(1):$ As a paracompact locally compact space is the topological sum of paracompact spaces, we can write each $Y_{\alpha}=\Sigma \mathcal{F}_{\alpha}$, where $\mathcal{F}_{\alpha}$ is a family of $\sigma$ - compact locally compact spaces. Suppose $\mathcal{G}$ is a basic open covering of $\square=<\omega_{1}-\square_{\alpha} Y_{\alpha}$. Given $x \in F=\Pi_{\alpha} F_{\alpha}$ with $x_{\alpha} \in F_{\alpha} \in \mathcal{F}_{\alpha} \quad$ for each $\alpha \in \mathcal{H}$, we apply $2.4(2)$ to choose a countable family $\mathcal{G}(x) \subseteq \mathcal{G}$ such that
(i). $q^{-1} q(x) \cap F \subseteq U G(x)$.

Putting $\sigma=U\{\operatorname{spt}(G): G \in \mathcal{G}(x)\}$, we see (i) implies $F(x) \subseteq U \mathcal{G}(x)$, where $F(x)=\left(\pi_{\alpha \in \sigma} F_{\alpha}\right) \times\left(\pi_{\alpha \in \omega_{1} \backslash \sigma} X_{\alpha}\right)$.

Now give each set $\mathfrak{F}_{\alpha}$ the discrete topology, and for each $x \in \square$, let $R(x)=\Pi_{\alpha} R(x)_{\alpha}$, where

$$
R(x)_{\alpha}=\left\{\begin{array}{ccc}
\left\{F(x)_{\alpha}\right\}, & \text { if } \alpha \in \operatorname{spt}(F(x)) \\
\mathcal{F}_{\alpha}, & \text { if } \alpha \notin \operatorname{spt}(F(x))
\end{array}\right.
$$

Then $R=\{R(x): x \in X\}$ is an open covering of $<\omega_{1}-\square_{\alpha \in \omega_{1}} \mathcal{Z}_{\alpha}$. From the proof of 1.3 , we may find a pairwise-disjoint open refinement $g$ of $R$ such that if $S \in S$ and if $\alpha \in \operatorname{spt}(S)$, then $\left|S_{\alpha}\right|=1$. For each $S \in \delta$ choose one $x_{S} \in \square$
such that $S \subseteq R\left(x_{S}\right)$, and let $U(S)=\Pi_{\alpha} U(S)_{\alpha}$ be defined by

$$
U(S)_{\alpha}= \begin{cases}F_{\alpha}, & \text { if } \alpha \in \operatorname{spt}(S) \text { and } S=\left\{F_{\alpha}\right\} \\ X_{\alpha}, & \text { if } \alpha \notin \operatorname{spt}(S) .\end{cases}
$$

Clearly $\left\{G \cap U(S): G \in \mathcal{G}\left(x_{S}\right), S \in S\right\}$ is a $\sigma-$ locally finite refinement of $\mathcal{G} . / /$
In reality 2.5 is true if we replace $<\omega_{1}-\square_{\alpha \in \omega_{1}} Y_{\alpha}$ by $<\omega_{1}-\square_{\alpha \in \mathcal{H}_{\alpha}}$ for any infinite $u$. However, in case $u>\omega_{1}$ the replacement is useless, because if $X_{\alpha}$ contains at least two points $\forall \alpha \in \omega_{2}$, then $<\omega_{1}-\square_{\alpha \in \omega_{2}} X_{\alpha}$ is not normal (see [1] and [2]).
83. Consistently paracompact.

In this section we will extend to $<\omega_{1}-\square_{\alpha} \in \omega_{1} X_{\alpha}$. a theorem of Kunen [5] known for $a_{\alpha \in \omega^{\prime}} X$.
3.1. THEOREM. [CH] If $X_{\alpha}$ is a paracompact locally compact scattered space for each $\alpha \in \omega_{1}$, then $-<\omega_{1}-\square_{\alpha} X_{\alpha}$ is paracompact.

Before proving 3.1 we need several definitions and lemmas. Recall that the Lindelof degree, $L(X)$, of a space $X$ is the least infinite cardinal $x$ such that each open covering of $X$ has a subcovering of cardinality at most $x$. The $G_{\delta}$-topology of a space $(X, \tau)$ is the topology $\tau^{\prime}$ on $X$ whose base is the set of all $G_{\delta}$-sets of $(X, \tau)$. When $X$ denotes $(X, \tau)$, then we let $X_{\delta}$ denote ( $X, \tau^{\prime}$ ) . Of course, $X_{\delta}$ is always a P-space.
3.2. LEMMA [7]. If $X$ is a scattered space, then $L(X)=L\left(X_{\delta}\right) \cdot / /$

The conclusion for the next lemma was obtained in [5] for countably many compact scattered factors case.
3.3. LEMMA. If $X_{\alpha}$ is a Lindelof scattered space for each $\alpha \in \omega_{1}$, then $\mathrm{L}\left(<\omega_{1}-\square_{\alpha} X_{\alpha}\right) \leq \underline{\underline{c}}$.

PROOF. Obviously $L\left(<\omega_{1}-\square_{\alpha} X_{\alpha}\right) \leq L\left(<\omega_{1}-\square_{\alpha}\left(X_{\alpha}\right)_{\delta}\right)$. According to 3.2 each $\left(X_{\alpha}\right)_{\delta}$ is a Lindelof scattered P-space. So, without loss of generality, we may assume each $X_{\alpha}$ is a P-space. Now the proof is similar to the proof of 1.3 . Just add a new condition
( $1 \frac{1}{2}$ ). $|u(v)| \leq c$
to the recursion hypothesis. In case 1 , observe that for each $\alpha \in \operatorname{spt}(U)$ we may take $\left|\mathfrak{F}_{\alpha}\right| \leq \omega$. Since $\omega \cdot \underline{c}=\underline{\underline{c}}$, ( $1 \frac{1}{2}$ ) holds. In case 2 , we have by recursion hypothesis $|u(\xi)| \leq \underline{c}^{\omega}=\underline{\underline{c}}$ whenever $\xi<\omega_{1}$. Obviously, the last paragraph of 1.3 shows that the pairwise-disjoint refinement $u\left(\omega_{1}\right)$ has cardinality at most $\omega_{1} \cdot \underline{\underline{c}}=\underline{\underline{c}}$. //

PROOF of 3.1. According to 2.5, we need only prove that $\nabla_{\alpha} X_{\alpha}$ is paracompact whenever $X_{\alpha}$ is a $\sigma$-compact locally compact scattered space for each $\alpha \in \boldsymbol{K}$. From 3.3, $L\left(<\omega_{1}-\square_{\alpha} X_{\alpha}\right) \leq \underline{c}=\omega_{1}$. From $2.2 \nabla_{\alpha} X_{\alpha}$ is a P-space with $L\left(\nabla_{\alpha} X_{\alpha}\right) \leq \omega_{1}$, because $q$ is continuous. It is well known and easy to prove (see [11]), that a $P$-space is paracompact if its Lindelof degree is at most $\omega_{1}$. So $\nabla_{\alpha} X_{\alpha}$ is paracompact. //

Question 2: Suppose that ${ }^{\omega}{ }_{\omega}$ is given the order topology. Is it consistent with $\omega_{1}<c$ that $<\omega_{1}-\square^{\omega}{ }^{1}\left({ }^{\omega} \omega\right)$ is normal?
3.4 REMARKS. Miller [9] proved that CH implies $<\omega_{1}-\square_{\alpha \in \omega_{1}} X_{\alpha}$ is paracompact whenever each $X_{\alpha}$ is a compact metrizable space. However, a stronger result can be found using the methods of [13]: The axiom $d=\omega_{1}$ implies $<\omega_{1}-\square_{\alpha \in \omega_{1}} X_{\alpha}$ is paracompact whenever each $X_{\alpha}$ is a $\sigma$ - compact locally compact space of weight at most $\omega_{1}$.

Question 3. Suppose that $\Pi^{\omega}{ }^{1}[0,1]$ is given the usual Tychonov product topology. Is it consistent with $\omega_{1}<d$ that $<\omega_{1}-\square^{\omega_{1}}\left(\pi{ }^{\omega}{ }^{\omega}[0,1]\right)$ is paracompact?

One might hope that forcing with the Cohen partial order FN ( $\mu, 2$ ) (see [6]) might yield, for $c f(x)>\omega$, a positive solution to our question 3. Indeed, each basic open set of $<\omega_{1}-\square^{\omega_{1}}\left(\pi^{\omega} 1[0,1]\right)$ can be considered as defined at some stage $\lambda \in \mu$. However, the criterion devised by Roitman [10], for proving the paracompactness of the nabla product, do not appear to be satisfied.

## 84. A non-paracompact box product

Kunen, applying a result due to Ar'hangelski, has observed an important relationship between paracompactness and the Lindelof degree.
4.1 LEMMA [51. Suppose that for each $n \in \omega, X_{n}$ is a compact space. If $\square_{n} X_{n}$ is paracompact, then $L\left(\square_{n} X_{n}\right) \leq c$.//

Recall that a space $X$ is called orderable provided its topology is the interval topology induced by a linear ordering of the set $X$. Let

$$
\begin{aligned}
& X^{*}=\{x \in X: x \text { has an immediate successor }\} \cup\{\sup X\}, \text { and } \\
& X_{*}=\{x \in X: x \text { has an immediate predecessor }\} \cup\{\inf X\} .
\end{aligned}
$$

A11 previous examples of non-paracompact box products of compact spaces (see [13]) use the same technique: Find a compact space $K$ such that its $G_{\delta}$-modification $K_{\delta}$ (see section 3) is not normal, then observe that $K_{\delta}$ embeds as a closed subspace of $\square^{\omega} K$. However, if $K$ is a compact orderable space, then $X_{\delta}$ is paracompact and $L\left(X_{\delta}\right) \leq \underset{X}{ }$ for each finite power $X$ of $K$ [14]. Therefore, the following represents a new method for obtaining non-paracompact box products.
4.2. EXAMPLE. There is a compact orderable space $T$ such that $\square^{\omega} T$ is not paracompact.

PROOF: Let $K=\stackrel{c}{=} 2$ be ordered lexicographically; i.e., by

$$
f<g \text { iff } f(\alpha)<g(\alpha), \text { where } \alpha=\inf \{\zeta \in \underline{f}: f(\zeta) \neq g(\zeta)\}
$$

Note that $K^{*} \cap K_{*}=\phi$. It is well-known that there is a family $\bar{u}=\left\{A_{\alpha}: \alpha \in \underline{c}\right\}$ of subsets of $\omega$ satisfying
(1). for each distinct pair $G_{0}, G_{1}$ of finite subsets of $G$ we have $\cap \mathrm{a}_{0} \backslash \cup \mathrm{a}_{1} \neq \phi$.
(G. is called an independent family of sets [4] and [6]). For each $f \in K$, define $\hat{\mathbf{f}} \in{ }^{\omega_{K}}$ by

$$
\hat{f}(n)(\alpha)=\left\{\begin{array}{ccc}
f(\alpha) & \text { if } & n \in A_{\alpha} \\
1-f(\alpha) & \text { if } & n \notin A_{\alpha}
\end{array}\right.
$$

for each $\alpha \in \subseteq$.
CLAIM 1. Suppose that $f, g \in K, f<g$, and $\alpha=\inf \{\zeta \in \underset{=}{f}:(\zeta)=g(\zeta)\}$.

Then the following are true:
Proof of claim 1.
(2). $\hat{f}(n)<\hat{g}(n)$ if $n \in A_{\alpha}$, and $\hat{g}(n)<\hat{f}(n)$ if $n \notin A_{\alpha}$.
(3). $\quad F \cap \pi_{n}[\inf \{\hat{f}(n), \hat{g}(n)\}, \sup \{\hat{f}(n), \hat{g}(n)\}]=\{\hat{f}, \hat{g}\}$.

The statement (2) is a consequence of the obvious $\hat{f}(n)(\zeta)=\hat{g}(n)(\zeta)$ if $\zeta<\alpha$. To see (3) suppose $h \in K \backslash\{f, g\}, \beta=\inf \{\zeta: f(\zeta) \neq h(\zeta)\}$, and $\gamma=\inf \{\zeta: g(z) \neq h(\zeta)\}$. We consider two cases:

Case 1. $h<f$ (or similarly, $g<h$ ): If $h<\dot{f}$, then (1) finds an $\overline{n \in A_{\alpha}} \cap A_{\beta} \cap A_{\gamma}$. For this $n$ (2) implies $\hat{h}(n)<\hat{f}(n)<\hat{g}(n)$. Therefore, $\hat{h}$ is not between $\hat{\mathbf{f}}$ and $\hat{g}$.

Case 2. $f<h<g$ : Since $\alpha=\beta=\gamma$ is impossible, either $\alpha \neq \beta$ or $\alpha \neq \gamma$. If $\alpha \neq \gamma$, then $f<h<g$ implies $\alpha<\beta$. Now (1) finds an $n \in A_{\alpha} \cap A_{\beta} \backslash A_{\gamma}$. For this $n$, (2) implies $\hat{f}(n)<\hat{g}(n)<\hat{h}(n)$. So $\hat{h} \notin[\hat{f}(n), \hat{g}(n)]$. The argument is similar when $\alpha \neq \gamma$. Thus, case 2, and hence the claim is proved.

Jefine $T=\left(\left(K \backslash\left(K^{*} \cup K_{*}\right) \times\{0,1\}\right) \cup\left(\left(K^{*} \cup K_{*}\right) \times\{0\}\right)\right.$, let $T$ be lexicographically ordered (so $T=T^{*} \cup T_{*}$ and $T^{*} \cap T_{*}=\phi$ ), and give $T$ the interval topology. For each $f \in K$ define $f^{\#{ }^{*}} \in{ }^{\omega} T$ by $f^{\#}(n)=\langle\hat{f}(n), 0\rangle$. Then we have
(4). for each $f, g \in K$ and each $n \in \omega, f^{\#}(n)<g^{\#}(n)$ iff $\hat{f}(n)<\hat{g}(n)$. Define $C=\left\{\mathrm{f}^{\#}: f \in K \backslash\left(K^{*} \cup K_{\star}\right)\right\}$.

CLAIM 2. $C$ is closed and discrete in $\square^{\omega}$.
Proof of claim 2. We suppose, by way of contradiction $x \in a^{\omega} T$ is a limit point of $C$. Define an open box neighborhood $U_{0}=\Pi_{n} U_{0}(n)$ of $x$ by

$$
U_{0}(n)= \begin{cases}{[\operatorname{lnf} T, x(n)]} & \text { if } x(n) \in T^{*} \\ {[x(n), \sup T]} & \text { if } x(n) \in T_{*}\end{cases}
$$

Since $U_{0}$ is an open neighborhood of $x$, chere is a $c_{0} \in U_{0} \cap c$. Now construct, inductively, for each positive $1 \in \omega$, an open box neighborhood $U_{i}=\Pi_{n} U_{i}(n)$ of $x$ and a point $c_{i} \in{ }^{\omega} T$ subject to the three conditions:
(5). $\quad U_{i}(n)= \begin{cases}{[x(n), \text { sup } T]} & \text { if } x(n) \in T_{*} \\ {[\text { inf } T,} & x(n)] \\ \text { if } x(n) \in T^{*} \backslash\left\{c_{j}(n): 0<j<1\right\} . \\ \left(c_{j-1},\right. & x(n)] \\ \text { if } x(n)=c_{j}(n) \text { and } 0<j<1 .\end{cases}$
(6). $c_{i} \in U_{i} \cap C$
(7). if $c \in U_{i} \cap C$, if $m \in \omega$, and if $c(m)=x(m)$, then there is a $j \leq 1$ such that $c_{j}=c$.

Now (5) can be reached because $c(n) \in T^{*} \forall n \in \omega \forall c \in C .{ }^{\prime}$ According to (2), if $c, c^{\prime} \in C$ and if $c(m)=c^{\prime}(m)$, then $c=c^{\prime}$. So (7) can be achieved. So we assume $U_{i}$ and $c_{i}$ are constructed $\forall i \in \omega$.

$$
\text { Define } V=\Pi_{n} V(n) \subseteq a^{\omega} T \text { by }
$$

$$
V(n)= \begin{cases}{[x(n), \sup T]} & \text { if. } x(n) \in T_{t} \\ {[\inf T, x(n)]} & \text { if } x(n) \in T^{*} \backslash\left\{c_{1}(n): 0<1 \in \omega\right\} \\ \cap_{j \leq i}\left(c_{j}(n), x(n)\right] & \text { if } x(n)=c_{i+1}(n) \text { and } i \in \omega .\end{cases}
$$

Then $V$ is an open neighborhood of $x$ and $V \subseteq \cap_{i \in \omega} U_{i}$. We consider two cases:

Case 3. $\mathcal{H}_{c} \in C \cap V$ and $m \in \omega$ with $c(m)=x(m):$ From (7) there is a $k \in \omega$ with $c_{k}=c$. Since $c \in U_{k}$, (5) shows $k=0$. Since $c \in V, V=U_{0}$. Let $d_{1}=c_{0}$ and define $d_{0} \in{ }^{\omega} T$ by

$$
d_{0}(n)= \begin{cases}\sup T & \text { if } x(n) \in T_{\dot{*}} \\ \operatorname{lnf} T & \text { if } x(n) \in T^{*}\end{cases}
$$

Since $x$ is a limit point of $C$, we may define inductively $d_{i} \in C \cap V$ for $i \in\{2,3,4\}$ by
(8). $d_{i}(n) \in \begin{cases}{\left[x(n), d_{i-1}(n)\right)} & \text { if } x(n) \in T_{*} \\ \left(d_{i-1}(n), x(n)\right] & \text { if } x(n) \in T^{*} \backslash\left\{d_{i-1}(n)\right\} \\ \left(d_{i-2}(n), x(n)\right] & \text { if } x(n)=d_{i-1} .\end{cases}$

Now (2) implies $d_{1}(n), d_{2}(n), d_{3}(n)$, and $d_{4}(n)$ are pairwise-distinct $\forall n \in \omega$. Since $c_{0} \neq d_{i} \in V \forall i>1, x(n) \neq d_{i}(n) \forall n \in \omega \forall i>1$. So we have
(9). $x(n) \in T_{*}$ implies $d_{4}(n)<d_{3}(n)<d_{2}(n)<d_{1}(n)$.
(10). $x(n) \in T_{*} \backslash\left\{d_{1}(n)\right\}$ implies $d_{1}(n)<d_{2}(n)<d_{3}(n)<d_{4}(n)$.
(11). $x(n)=d_{1}(n)$ imp1ies $d_{2}(n)<d_{3}(n)<d_{4}(n)<d_{1}(n)$.

Therefore, $d_{3} \in \Pi_{n}\left[\inf \left\{d_{2}(n), d_{4}(n)\right\}, \sup \left\{d_{2}(n), d_{4}(n)\right\}\right]$ which contradicts (3).

Case 4. $c \in C \cap V$ implies $x(n) \neq c(n) \forall n \in \omega$. Choose $d_{2} \in C \cap V$ randomly, and define $d_{i}$ for $i \in\{3,4\}$ as in (8). The argument of the previous paragraph (neglecting $d_{1}$ of course) works here to achieve a contradiction. Thus, case 4, and hence claim 2, is true.

According to claim 2, it is sufficient to show $|C|=2 \underline{c}$. But this follows
since (4) shows $|C|=\left|K \backslash\left(K^{*} \cup K_{*}\right)\right|$. However, $K^{*} \cup K_{*}$ is exactly $\left\{f \epsilon^{\frac{c}{=}} 2\right.$ : $f$ is constant on a tail\}. Therefore, $\left|K \backslash\left(K^{*} \cup K_{*}\right)\right|=2 \stackrel{c}{c}^{\text {* }}$. So $\quad 2^{c} \leq\left|L\left(0^{\omega} T\right)\right| \leq$ $\left|\square^{\omega} T\right|=2^{\frac{c}{c}}$.//
4.3. COROLLARY: There is a compact orderable space $T$ such that $a^{\omega} T$ is not paracompact.

PROOF. Apply 4.1 to $4.2: / /$
4.4. COROLLARY $[2 \stackrel{c}{=}=\underline{=}]$ : There is a compact orderable space $T$ such that $\square^{\omega} T$ is not normal.

PROOF. In the example 4.2, $\left|K^{*} \cup K_{*}\right|=2^{c}$ and $K^{*} U K_{*}$ is dense in $K$. Therefore, $\square^{\omega} T$ has a dense set of cardinal $c^{\omega}=c$. Since $a^{\omega} T$ has a closed discrete subset of cardinal $\underset{2}{=}$, the F. B. Jones lemma (see [4]) shows $a^{\omega} T$ is not norma1. //

Question 3: Suppose $X$ is a compact space. Does $X_{\delta}$ normal imply $L\left(X_{\delta}\right) \leq \underline{c}$ ? [Observe that $\left.L\left(\square^{\omega} X\right)=L\left(\square^{\omega}\left(X_{\delta}\right)\right)\right]$.
4.5. Remarks: Independently, Kunen has shown that the axiom in 4.4 is unnecessary. Specifically, he proved ${ }^{\omega}{ }^{\omega} T$ is not normal when $T$ is the lexicographic ordered product $\quad{ }^{\omega_{1}+1} 2$.

## §5. On the full box product

At present, we know of no answers even consistent with ZFC to the question, "Is $\quad{ }^{\mathcal{H}} \omega+1$ paracompact?" for any uncountable cardinal $x$. An affirmative answer for some full box product $\square_{\alpha} X_{\alpha}$ of compact spaces would seem to require an intermediate object like the nabla products $\nabla_{\ell, \alpha_{\alpha}}$ of section 2. By "intermediate" we mean that $\nabla_{\ell}$ can be shown paracompact under various hypothesis on the $X_{\alpha}$, and that $\nabla_{\Omega}$ paracompact ought to imply $\square$ is paracompact.

If the ideal \& contains an uncountable set, then the point-inverses of the map $q: \nabla_{\ell} \rightarrow \square$ are closed and contain closed homeomorphs of an uncountable box product of the spaces $X_{\alpha}$. Therefore, $\mathcal{I}$ should contain no uncountable sets.

Even in the case $d$ contains an infinite set, there are difficulties. For $\ell=\left[\omega_{1}\right]^{\leq \omega}$, van Douwen has offered in [3] the following reasons why $\nabla_{\mathscr{g}}$ is useless for our purposes: 1). $\nabla_{\ell}$ is rarely a P-space; 2). The map $q$ is rarely closed and its point-inverses are not Lindelof (so Michael's theorem can
not be applied as we did in 2.5); 3). [ $\left.2^{\omega} 1=\omega_{2}\right]$ There is a compact space $K$ such that ${ }^{\nabla}{ }_{9}^{\omega} 1_{\mathrm{K}}$ is paracompact but ${ }_{\square}^{{ }^{\omega} 1^{1} \mathrm{~K}}$ is not normal.

It is clear that $\mathscr{J}=\left[h^{<}{ }^{<\omega}\right.$ is likely our only hope - this is what we have studied recently. Although the topology on $\nabla_{\Omega, \alpha} X_{\alpha}$ is finer than that considered in section 2 , we risk confusion by using the same symbol $\nabla_{\alpha} X_{\alpha}$ to denote it. Again $\nabla_{\alpha} X_{\alpha}$ is rarely a P-space and so paracompactness is not 'easily proved; however, we have shown (proofs will appear elsewhere)
5.1. PROPOSITION. [MA] If $x<c$ and if $X_{\alpha}$ is a compact first countable space for each $\alpha \in \omega_{1}$, then $\nabla_{\alpha} X_{\alpha}$ is paracompact. //

The quotient map $q$ is probably not closed in this case as well, and certainly point-inverses are not Lindelof. However, these results are not needed to show that $\nabla$ paracompact implies $\square$ is paracompact. What is needed is the following statement:
(\#). If $\mathcal{G}$ is an open covering of $\square$, then for each $x \in \square$ there is an open neighborhood of $H_{x}$ of $q(x)$ in $\nabla$ and an open locally-finite family $\delta_{x}$ covering $q(x)^{-1}$ in $\square$ such that $\delta_{x}$ refines $G \mid q^{-1}\left(H_{x}\right)$.

I cannot yet prove \#, but I do have an approximation to $i+$ -

Our proof of 5.2 shows various kinds of disjoint closed sets of $\square$ can be separated.
