SOME INEQUALITIES CONCERNING THE CYCLIC AND RADIAL VARIATIONS OF A PLANE PATH-CURVE

JOSEF KRÁL, Praha

(Received November 5, 1962)

Let ψ be a path-curve in the Euclidean plane E_2 , $z \in E_2$. Given real numbers $r > 0$ and α write $\mu_r^\psi(\alpha; z)$ for the number of points at which ψ meets the segment $S_r^\alpha(z) = \{\zeta; \zeta = z + \varrho \exp i\alpha, 0 < \varrho < r\}$. Then $\mu_r^\psi(\alpha; z)$ is (Lebesgue) measurable with respect to α and one may put $v_r^\psi(z) = \int_0^{2\pi} \mu_r^\psi(\alpha; z) d\alpha$. Further let $v^\psi(\varrho; z)$ stand for the number of points at which ψ meets the circle $\{\zeta; |\zeta - z| = \varrho\}$, $v^\psi(\varrho; z)$ being measurable with respect to ϱ one may introduce the integral $u_r^\psi(z) = \int_0^r v^\psi(\varrho; z) d\varrho$. Suppose now that β is a fixed real number and ψ is a path-curve through z not meeting $\bigcup_{\alpha} S_{2r}^\alpha(z)$, $\alpha \in (\beta - \delta, \beta + \delta) \cup (\beta + \pi - \delta, \beta + \pi + \delta)$, where $0 < \delta < \pi/2$. Then

- (1)
$$\sup_{0 < \varrho < r} \varrho^{-1} u_\varrho^\psi(z) \leq K[v_r^\psi(z) + \sup_{0 < \varrho < r} v_{2\varrho}^\psi(z + \varrho \exp i\beta)],$$
- (2)
$$\sup_{0 < \varrho < r} v_r^\psi(z + \varrho \exp i\beta) \leq M[v_{2r}^\psi(z) + \sup_{0 < \varrho < 2r} \varrho^{-1} u_\varrho^\psi(z)]$$

with constants K, M depending on δ only. These inequalities are useful in connection with investigations concerning the boundary behaviour of the logarithmic potential of the double distribution.

1

In this paragraph some auxiliary results concerning functions of a real variable are collected. They will be used in § 2 below for the proof of some inequalities implying (1) and (2). The term interval will be used to mean any non-void convex subset of the real line E_1 . The variation of a (finite real-valued) function f on a compact interval K , to be denoted by $\text{var } [f; K]$, is defined as usual. If f is a function on an arbitrary interval J , we put $\text{var } [f; J] = \sup_K \text{var } [f; K]$, K ranging over all compact intervals in J . For every set $G \subset J$ open in J put $\text{var } [f; G] = \sum_I \text{var } [f; I]$, I ranging over all components of G . Letting, as usual, $\text{var } [f; M] = \inf_G \text{var } [f; G]$, $G \supset M$, G open in J , we extend $\text{var } f$ to a Carathéodory outer measure defined for any $M \subset J$,

which, if restricted to the system of all var f – measurable subsets in J , represents a measure (cf., e.g., [4]). The integral $\int_M H d \text{var } f$ of a (real-valued, possibly infinite) function H is always to be interpreted as the (Lebesgue-Stieltjes) integral with respect to this measure. The following known theorem will be frequently used below.

1.1. Let f be a continuous function of finite variation on the interval I and let F be a (possibly infinite) function on $f(I)$. For every $x \in E_1$ denote by $N_f(x)$ the number of points in $f^{-1}(x)$ ($0 \leq N_f(x) \leq +\infty$). Then N_f is Lebesgue measurable on E_1 and

$$(3) \quad \int_I F(f) d \text{var } f = \int_{f(I)} F(x) N_f(x) dx$$

provided the integral on the left-hand side exists. (The integral on the right-hand side is the ordinary Lebesgue integral.)

A proof of this assertion in the case that I is compact can be found in [1]. It is easily seen that the theorem extends to the case described above.

We shall also need the following formulation of the Banach theorem (cf. [3], part V, § V. 1):

1.2. Let f be a continuous function on the interval I . Then

$$\text{var } [f; I] = \int_{f(I)} N_f(x) dx \left(= \int_{-\infty}^{\infty} N_f(x) dx \right),$$

N_f having the same meaning as in 1.1.

1.3. Lemma. Let f, h be continuous functions on $\langle a, b \rangle = \{x; a \leq x \leq b\}$ and suppose that $\text{var } [f; \langle a, b \rangle] < +\infty$. Let $D = \{a = x_0 < \dots < x_n = b\}$ be an arbitrary subdivision of $\langle a, b \rangle$ and suppose that $\xi_i \in \langle x_{i-1}, x_i \rangle$ ($1 \leq i \leq n$). Then

$$\sum_i h(\xi_i) |f(x_i) - f(x_{i-1})| \rightarrow \int_a^b h d \text{var } f$$

as $\max_i (x_i - x_{i-1}) \rightarrow 0$.

Proof. Let us agree to write $|D| = \max_i (x_i - x_{i-1})$. Put $s(a) = 0$, $s(x) = \text{var } [f; \langle a, x \rangle]$, $a < x \leq b$. Then s is non-decreasing and

$$\sum_i h(\xi_i) [s(x_i) - s(x_{i-1})] \rightarrow \int_a^b h d \text{var } f \text{ as } |D| \rightarrow 0.$$

On the other hand, $s(x_i) - s(x_{i-1}) \geq |f(x_i) - f(x_{i-1})|$ and

$$\begin{aligned} & \left| \sum_i h(\xi_i) [s(x_i) - s(x_{i-1})] - \sum_i h(\xi_i) |f(x_i) - f(x_{i-1})| \right| \leq \\ & \leq \max_{a \leq x \leq b} |h(x)| \cdot \{ \text{var } [f; \langle a, b \rangle] - \sum_i |f(x_i) - f(x_{i-1})| \} \rightarrow 0 \end{aligned}$$

as $|D| \rightarrow 0$ (cf. [2], chap. VIII, theorem 2).

We shall say that f has locally finite variation on J provided $\text{var}[f; K] < +\infty$ for every compact interval $K \subset J$.

1.4. Lemma. *Let f be a continuous function of locally finite variation on the interval J . Let F be a function on $f(J)$ and suppose that F possesses a continuous derivative on $f(J)$. Then*

$$(4) \quad \text{var}[F(f); J] = \int_J |F'(f)| \, d \text{var } f.$$

Proof. Let $\langle a, b \rangle$ be an arbitrary compact interval contained in J ($a < b$). We shall prove that

$$(5) \quad \text{var}[F(f); \langle a, b \rangle] = \int_a^b |F'(f)| \, d \text{var } f.$$

The rest of the proof is obvious and will be left to the reader. Consider an arbitrary subdivision $D = \{a = x_0 < \dots < x_n = b\}$ of $\langle a, b \rangle$. Between $f(x_i)$ and $f(x_{i-1})$ such a point y_i can be found that $F(f(x_i)) - F(f(x_{i-1})) = F'(y_i)(f(x_i) - f(x_{i-1}))$. Since f is continuous we have a $\xi_i \in \langle x_{i-1}, x_i \rangle$ with $f(\xi_i) = y_i$ ($1 \leq i \leq n$). We have thus

$$\sum_i |F(f(x_i)) - F(f(x_{i-1}))| = \sum_i |F'(f(\xi_i))| \cdot |f(x_i) - f(x_{i-1})|.$$

Making $|D| \rightarrow 0$ we obtain on account of 1.3 the formula (5) (cf. also [2], chap. VIII, theorem 2).

1.5. Lemma. *Let f, g be continuous functions of locally finite variation on the interval I . If h is a continuous non-negative function on I then*

$$(6) \quad \int_I h \, d \text{var}(f \cdot g) \leq \int_I h|f| \, d \text{var } g + \int_I h|g| \, d \text{var } f.$$

Proof. It is sufficient to prove that, for any compact interval $\langle a, b \rangle \subset I$,

$$(7) \quad \text{var}[f \cdot g; \langle a, b \rangle] \leq \int_a^b |f| \, d \text{var } g + \int_a^b |g| \, d \text{var } f.$$

Let $D = \{a = x_0 < \dots < x_n = b\}$ be an arbitrary subdivision of $\langle a, b \rangle$. Then

$$\begin{aligned} & \sum_i |f(x_i)g(x_i) - f(x_{i-1})g(x_{i-1})| \leq \\ & \leq \sum_i |f(x_i)| \cdot |g(x_i) - g(x_{i-1})| + \sum_i |g(x_{i-1})| \cdot |f(x_i) - f(x_{i-1})|. \end{aligned}$$

Making $|D| \rightarrow 0$ we obtain the inequality (7) (cf. 1.3 and [2], chap. VIII, § 2, theorem 2).

1.6. Lemma. Let f, g be continuous functions of finite variation on the interval I , $0 < k \leq |f| \leq K, |g| \leq |f|$. If h is a continuous function of locally finite variation on I then

$$(8) \quad \text{var} [\text{arccotg} (g + fh); I] \leq L\{\text{var} [g; I] + \text{var} [f; I] + \text{var} [\text{arccotg} h; I]\}$$

with constant L depending on constants k, K only.

Proof. By 1.4 and 1.5 we obtain

$$\begin{aligned} \text{var} [\text{arccotg} (g + fh); I] &= \int_I \frac{1}{1 + (g + fh)^2} d \text{var} (g + fh) \leq \\ &\leq \int_I \frac{1}{1 + (g + fh)^2} d \text{var} g + \int_I \frac{|f|}{1 + (g + fh)^2} d \text{var} h + \int_I \frac{|h|}{1 + (g + fh)^2} d \text{var} f \leq \\ &\leq \text{var} [g; I] + \int_I \frac{|f| d \text{var} h}{1 + (|f| \cdot |h| - |g|)^2} + \int_I \frac{|h| d \text{var} f}{1 + (|f| \cdot |h| - |g|)^2}. \end{aligned}$$

We have

$$\frac{|f|}{1 + (|f| \cdot |h| - |g|)^2} \leq \frac{K}{1 + h^2} \cdot \frac{1 + h^2}{1 + (|f| \cdot |h| - |g|)^2} \leq K \cdot k_1 \cdot \frac{1}{1 + h^2},$$

where we put

$$k_1 = \max \left[2, \sup_{y>1} \frac{1 + y^2}{1 + k^2(y - 1)^2} \right].$$

Hence

$$\int_I \frac{|f| d \text{var} h}{1 + (|f| \cdot |h| - |g|)^2} \leq K \cdot k_1 \cdot \int_I \frac{d \text{var} h}{1 + h^2} = K \cdot k_1 \text{var} [\text{arccotg} h; I].$$

In a similar way

$$\begin{aligned} \frac{|h|}{1 + (|f| \cdot |h| - |g|)^2} &\leq \max \left[1, \sup_{y>1} \frac{y}{1 + k^2(y - 1)^2} \right] \leq k_1, \\ \int_I \frac{|h| d \text{var} f}{1 + (|f| \cdot |h| - |g|)^2} &\leq k_1 \text{var} [f; I]. \end{aligned}$$

We conclude that

$$\text{var} [\text{arccotg} (g + fh); I] \leq \text{var} [g; I] + k_1\{\text{var} [f; I] + K \text{var} [\text{arccotg} h; I]\}$$

and (8) is established.

1.7. Lemma. Let v be a non-negative integrable function on $\langle 0, q \rangle$. Then, for any $x \in \langle 0, q \rangle$,

$$\int_0^q \frac{x}{\xi^2 + x^2} v(\xi) d\xi \leq \frac{\pi}{2} \sup_{0 < x < q} \frac{1}{x} \int_0^x v(\xi) d\xi.$$

Proof. Put $F(0) = 0$, $F(x) = \int_0^x v(\xi) d\xi$ ($0 < x \leq q$), $k = \sup_{0 < x < q} x^{-1} F(x)$. Integrating by parts we obtain for any $x \in (0, q) = \{x; 0 < x \leq q\}$ the estimate

$$\begin{aligned} \int_0^q \frac{x}{\xi^2 + x^2} v(\xi) d\xi &= \frac{x}{q^2 + x^2} F(q) + 2x \int_0^q \frac{\xi F(\xi)}{(\xi^2 + x^2)^2} d\xi \leq \\ &\leq \frac{kqx}{q^2 + x^2} + 2kx \int_0^q \frac{\xi^2}{(\xi^2 + x^2)^2} d\xi = k \operatorname{arctg} \frac{q}{x} < k \frac{\pi}{2}. \end{aligned}$$

2

The term path will be used to denote a continuous complex-valued function defined on an interval. We shall suppose throughout that ψ is a fixed path on the interval J . Further we shall fix a point $z \in E_2$. For every $G \subset J$ and $x \in E_1$ we denote by $\mu^\psi(x; z, G)$ the number (possibly zero or infinite) of points in $\{t; t \in G, |\psi(t) - z| > 0, \psi(t) - z = |\psi(t) - z| \exp ix\}$.

2.1. Lemma. *Let $I \subset J$ be an interval, $|\psi(t) - z| > 0$ for every $t \in I$. Let ϑ_I be a real-valued continuous function on I with*

$$(9) \quad \psi(t) - z = |\psi(t) - z| \exp i\vartheta_I(t), \quad t \in I.$$

Then $\mu^\psi(x; z, I)$ is Lebesgue measurable with respect to x and

$$\int_0^{2\pi} \mu^\psi(x; z, I) dx = \operatorname{var} [\vartheta_I; I].$$

Proof. We shall write simply ϑ instead of ϑ_I . Let N_ϑ have the meaning described in 1.1. It is easily seen that

$$\mu^\psi(x; z, I) = \sum_{n=-\infty}^{\infty} N_\vartheta(x + 2n\pi).$$

N_ϑ being measurable the same is true about $\mu^\psi(x; \dots)$ and we have by 1.2

$$\operatorname{var} [\vartheta; I] = \int_{-\infty}^{\infty} N_\vartheta(x) dx = \int_0^{2\pi} \mu^\psi(x, \dots) dx.$$

2.2. Lemma. *Let G be open in J and denote by \mathfrak{S} the system of all components of the set $\{t; t \in G, |\psi(t) - z| > 0\}$. For every $I \in \mathfrak{S}$ fix a continuous real-valued function ϑ_I on I with (9). Then $\mu^\psi(x; z, G)$ is measurable and*

$$\int_0^{2\pi} \mu^\psi(x; z, G) dx = \sum_{I \in \mathfrak{S}} \operatorname{var} [\vartheta_I; I].$$

Proof. This assertion follows at once from 2.1 on account of the equality

$$\mu^\psi(x; z, G) = \sum_{I \in \mathfrak{S}} \mu^\psi(x; z, I).$$

2.3. Definition. Let G be open in J . We define

$$v^\psi(z; G) = \int_0^{2\pi} \mu^\psi(x; z, G) dx.$$

2.4. Remark. The definition 2.3 is justified by 2.2. From geometric reasons the quantity $v^\psi(z; G)$ could be called the cyclic variation of $\psi | G$ with respect to z , while the function $\mu^\psi(x; z, G)$ could be called the cyclic indicatrix of $\psi | G$ with respect to z .

We shall write $v_r^\psi(z)$ instead of $v^\psi(z; G_r)$ where

$$G_r = \{t; t \in J, |\psi(t) - z| < r\}.$$

Given $G \subset J$ and $\varrho > 0$ we shall denote by

$$v^\psi(\varrho; z, G) \quad (0 \leq v^\psi(\varrho; z, G) \leq +\infty)$$

the number of points in $\{t; t \in G, |\psi(t) - z| = \varrho\}$.

2.5. Lemma. Let G be open in J and write \mathfrak{C} for the system of all components of $\{t; t \in G, |\psi(t) - z| > 0\}$. Then $v^\psi(\varrho; z, G)$ is measurable with respect to ϱ and

$$(10) \quad \int_0^\infty v^\psi(\varrho; z, G) d\varrho = \sum_{I \in \mathfrak{C}} \text{var}_t [|\psi(t) - z|; I].$$

Proof. For every $I \in \mathfrak{C}$, $v^\psi(\varrho; z, I)$ is measurable and, on account of 1.2,

$$\int_0^\infty v^\psi(\varrho; z, I) d\varrho = \text{var}_t [|\psi(t) - z|; I].$$

Noting that $v^\psi(\varrho; z, G) = \sum_{I \in \mathfrak{C}} v^\psi(\varrho; z, I)$ we obtain (10).

2.6. Definition. Let G be open in J . We define

$$u^\psi(z; G) = \int_0^\infty v^\psi(\varrho; z, G) d\varrho.$$

2.7. Remark. This definition is justified by 2.5. The quantity $u^\psi(z; G)$ could be called the radial variation of $\psi | G$ with respect to z and the function $v^\psi(\varrho; z, G)$ could be called the radial indicatrix of $\psi | G$ with respect to z . We shall write $u_r^\psi(z)$ instead of $u^\psi(z; G_r)$ where $G_r = \{t; t \in J, |\psi(t) - z| < r\}$. Thus $u_r^\psi(z) = \int_0^r v^\psi(\varrho; z, J) d\varrho$.

2.8. Theorem. Let ψ be a path on J , $\beta \in E_1$, $z \in E_2$, $0 < \varrho \leq r$, $\zeta = z + \varrho \exp i\beta$. Suppose that $z \pm x \exp i\alpha \notin \psi(J)$ whenever $0 < x \leq r$, $|\alpha - \beta| < \delta$ ($0 < \delta < \pi/2$) and put $G = \{t; t \in J, 0 < |\psi(t) - z| < r\}$. Then

$$(11) \quad v^\psi(\zeta; G) \leq M \{v_r^\psi(z) + \sup_{0 < x \leq r} x^{-1} u_x^\psi(z)\}$$

with M depending on δ only.

Proof. We may suppose that $z = 0$, $\beta = 0$. Let \mathfrak{E} be the system of all components of G . For every $I \in \mathfrak{E}$ and $\varrho \in \langle 0, r \rangle$ denote by $\vartheta_I(t, \varrho)$ a continuous function (of the variable t) on I with

$$(12) \quad \psi(t) - \varrho = |\psi(t) - \varrho| \cdot \exp i\vartheta_I(t, \varrho), \quad t \in I.$$

We have then

$$(13) \quad \sin \vartheta_I(t, \varrho) = \frac{\operatorname{Im} [\psi(t) - \varrho]}{|\psi(t) - \varrho|} = \frac{\operatorname{Im} \psi(t)}{|\psi(t) - \varrho|},$$

$$(14) \quad \begin{aligned} \sin [\vartheta_I(t, \varrho) - \vartheta_I(t, 0)] &= \frac{|\psi(t)|}{|\psi(t) - \varrho|} \cdot \operatorname{Im} \frac{\psi(t) - \varrho}{\psi(t)} = \\ &= \frac{|\psi(t)|}{|\psi(t) - \varrho|} \cdot \frac{\operatorname{Im} [|\psi(t)|^2 - \varrho \overline{\psi(t)}]}{|\psi(t)|^2} = \frac{\varrho \operatorname{Im} \psi(t)}{|\psi(t)| \cdot |\psi(t) - \varrho|} \end{aligned}$$

so that

$$(15) \quad \frac{\sin \vartheta_I(t, \varrho)}{\sin [\vartheta_I(t, \varrho) - \vartheta_I(t, 0)]} = \frac{|\psi(t)|}{\varrho}, \quad t \in I, \quad \varrho \in \langle 0, r \rangle$$

(which, in fact, is the elementary sine theorem applied to the triangle $0, \varrho, \psi(t)$). Noting that

$$\psi(G) \cap \{\varrho \exp i\alpha; |\varrho| \leq r, |\alpha| < \delta\} = \emptyset$$

we obtain

$$(16) \quad |\sin \vartheta_I(t, 0)| = \frac{|\operatorname{Im} \psi(t)|}{|\psi(t)|} > \sin \delta, \quad t \in G.$$

Fix now an $I \in \mathfrak{E}$. From (15) we conclude that

$$\frac{\varrho}{|\psi(t)|} = \cos \vartheta_I(t, 0) - \cotg \vartheta_I(t, \varrho) \cdot \sin \vartheta_I(t, 0)$$

whence

$$\cotg \vartheta_I(t, \varrho) = \cotg \vartheta_I(t, 0) - \sin^{-1} \vartheta_I(t, 0) \cdot \frac{\varrho}{|\psi(t)|}, \quad t \in I.$$

Defining the function $\tilde{\vartheta}$ on I by

$$\tilde{\vartheta}(t) = \operatorname{arccotg} \left\{ \cotg \vartheta_I(t, 0) - \sin^{-1} \vartheta_I(t, 0) \cdot \frac{\varrho}{|\psi(t)|} \right\}, \quad t \in I,$$

we observe easily that the difference $\vartheta_I(t, \varrho) - \tilde{\vartheta}(t)$ must reduce to a constant on I . Hence

$$(17) \quad \operatorname{var}_t [\vartheta_I(t, \varrho); I] = \operatorname{var} [\tilde{\vartheta}(t); I].$$

Our aim being to prove (11) we may clearly suppose that $v_r^\psi(z) + \sup_{0 < x \leq r} x^{-1} \cdot u_x^\psi(z) < +\infty$. In particular,

$$v_r^\psi(z) = \sum_{I \in \mathfrak{G}} \text{var} [\vartheta_I(t, 0); I] < +\infty,$$

$$u_r^\psi(z) = \sum_{I \in \mathfrak{G}} \text{var} [|\psi(t)|; I] = \int_0^\infty v^\psi(\xi; 0, G) d\xi < +\infty$$

(cf. 2.2 and 2.5). Next we use 1.6 concluding that

$$(18) \quad \text{var} [\tilde{\vartheta}; I] \leq L \left\{ \text{var} [\cotg \vartheta_I(t, 0); I] + \text{var} [\sin^{-1} \vartheta_I(t, 0); I] + \text{var}_t \left[\text{arccotg} \frac{\varrho}{|\psi(t)|}; I \right] \right\}$$

with L depending on δ only. Applying 1.4 we obtain (cf. also (16))

$$(19) \quad \text{var} [\cotg \vartheta_I(t, 0); I] \leq \sin^{-2} \delta \cdot \text{var} [\vartheta_I(t, 0); I],$$

$$(20) \quad \text{var} [\sin^{-1} \vartheta_I(t, 0); I] \leq \sin^{-2} \delta \cdot \text{var} [\vartheta_I(t, 0); I],$$

$$(21) \quad \text{var}_t \left[\text{arccotg} \frac{\varrho}{|\psi(t)|}; I \right] = \int_I \frac{\varrho}{\varrho^2 + |\psi|^2} d \text{var} |\psi|.$$

From (17)–(21) we derive (cf. 2.2)

$$(22) \quad v^\psi(\varrho; G) = \sum_{I \in \mathfrak{G}} \text{var}_t [\vartheta_I(t, \varrho); I] \leq \leq 2L \sin^{-2} \delta \left\{ v_r^\psi(0) + \frac{1}{2} \int_G \frac{\varrho}{\varrho^2 + |\psi|^2} d \text{var} |\psi| \right\}.$$

By 1.1 and 1.7 it follows

$$\begin{aligned} \int_G \frac{\varrho}{\varrho^2 + |\psi|^2} d \text{var} |\psi| &= \int_0^r \frac{\varrho}{\varrho^2 + \xi^2} v^\psi(\xi; 0, G) d\xi \leq \frac{\pi}{2} \sup_{0 < x < r} x^{-1} \int_0^x v^\psi(\xi; 0, G) d\xi = \\ &= (\text{cf. 2.6 and 2.7}) = \frac{\pi}{2} \sup_{0 < x < r} x^{-1} u_x^\psi(0) \end{aligned}$$

which together with (22) gives

$$v^\psi(\varrho; G) \leq 2L \sin^{-2} \delta \left\{ v_r^\psi(0) + \frac{\pi}{4} \sup_{0 < x < r} x^{-1} u_x^\psi(0) \right\}.$$

We see that it is sufficient to put $M = 2L \sin^{-2} \delta$ to satisfy (11).

2.9. Remark. Observing that $\{t; |\psi(t) - \zeta| < \frac{1}{2}r\} \subset \{t; |\psi(t) - z| < r\}$ whenever $\zeta = z + \varrho \exp i\beta$ with $\varrho \in (0, r/2)$ we obtain as a corollary of 2.8 the inequality

$$\sup_{0 < \varrho < \frac{1}{2}r} v_{r/2}^\psi(z + \varrho \exp i\beta) \leq M [v_r^\psi(z) + \sup_{0 < x < r} x^{-1} u_x^\psi(z)]$$

(compare (2)).

2.10. Theorem. Let ψ be a path on J , $z \in E_2$, $r > 0$, $\beta \in E_1$, $\zeta = z + r \exp i\beta$. Suppose that $z \pm \varrho \exp i\alpha \notin \psi(J)$ whenever $0 < \varrho < r$, $|\alpha - \beta| < \delta$ ($0 < \delta < \pi/2$) and put $G = \{t; t \in J, 0 < |\psi(t) - z| < r\}$. Then

$$(23) \quad r^{-1}u_r^\psi(z) \leq K[v_r^\psi(z) + v^\psi(\zeta; G)]$$

with K depending on δ only.

Proof. We suppose again that $z = 0$, $\beta = 0$. Let \mathfrak{C} , $\vartheta_I(t, \varrho)$ ($\varrho \in \langle 0, r \rangle$) have the same meaning as in the proof of 2.8. We may assume that

$$v_r^\psi(0) = \sum_{I \in \mathfrak{C}} \text{var} [\vartheta_I(t, 0); I] < +\infty,$$

$$v^\psi(\zeta; G) = \sum_{I \in \mathfrak{C}} \text{var}_t [\vartheta_I(t, r); I] < +\infty.$$

Fix now an $I \in \mathfrak{C}$ and write $\vartheta_I(t, r) = g(t)$, $\vartheta_I(t, r) - \vartheta_I(t, 0) = f(t)$, $\sin g = \tilde{g}$, $F = \sin^{-1}$, $F(f) = \tilde{f}$. Then $\text{var} \tilde{f} \tilde{g} \leq \sup |\tilde{f}| \text{var} \tilde{g} + \sup |\tilde{g}| \text{var} \tilde{f}$. Clearly, $\sup |\tilde{g}| \leq 1$; (14) and (16) imply $|\tilde{f}| < \sin^{-1} \delta$. $(|\psi| + r)/r \leq 2 \sin^{-1} \delta$. Further we have by 1.4 $\text{var} \tilde{f} \leq \sup |F'(f)| \text{var} f \leq 4 \sin^{-2} \delta \text{var} f$, $\text{var} \tilde{g} \leq \text{var} g$. Consequently, $\text{var} \tilde{f} \tilde{g} \leq 2 \sin^{-2} \delta (\text{var} g + 2 \text{var} f)$. Hence it follows on account of (15) that $r^{-1} \text{var} [|\psi(t)|; I] = \text{var}_t [\{\sin \vartheta_I(t, r)\} / \{\sin [\vartheta_I(t, r) - \vartheta_I(t, 0)]\}; I] \leq 2 \sin^{-2} \delta \cdot \{3 \text{var}_t [\vartheta_I(t, r); I] + \text{var}_t [\vartheta_I(t, 0); I]\}$ for every $I \in \mathfrak{C}$. On account of 2.5 (cf. also 2.6 and 2.7) and 2.2 (cf. also 2.3 and 2.4) we obtain $r^{-1} \cdot u_r^\psi(0) = \sum_{I \in \mathfrak{C}} r^{-1} \cdot \text{var}_t [|\psi(t)|; I] \leq 2 \sin^{-2} \delta \{3 \sum_{I \in \mathfrak{C}} \text{var}_t [\vartheta_I(t, r); I] + \sum_{I \in \mathfrak{C}} \text{var} [\vartheta_I(t, 0); I]\} = 2 \sin^{-2} \delta \cdot \{3v^\psi(r; G) + v^\psi(0)\}$. We see that it is sufficient to put $K = 6 \sin^{-2} \delta$ to satisfy (23).

2.11. Remark. Given $\zeta = z + \varrho \exp i\beta$ with $0 < \varrho < \frac{1}{2}r$ then $G_\varrho = \{t; |\psi(t) - z| < \varrho\} \subset \{t; |\psi(t) - \zeta| < 2\varrho\}$ and, consequently, $v^\psi(\zeta; G_\varrho) \leq v_{2\varrho}^\psi(\zeta)$. Hence it follows on account of 2.10 $\sup_{0 < \varrho < r/2} \varrho^{-1} u_\varrho^\psi(z) \leq K[v_{r/2}^\psi(z) + \sup_{0 < \varrho < r/2} v_{2\varrho}^\psi(z + \varrho \exp i\beta)]$ (compare (1)).

2.12. Remark. The inequalities (1), (2) make it possible to establish simple necessary and sufficient conditions for the existence of non-tangential limits of the logarithmic potential of a continuous double distribution. Such conditions were announced in [5] where, however, in theorem 1 the assumption that the path-curve φ be rectifiable is to be completed.

Резюме

НЕКОТОРЫЕ НЕРАВЕНСТВА ОТНОСИТЕЛЬНО ЦИКЛИЧЕСКОЙ И РАДИАЛЬНОЙ ВАРИАЦИИ ПЛОСКОГО ПУТИ

ИОСЕФ КРАЛ (Josef Král), Прага

Путем разумеется непрерывное отображение одномерного интервала J в евклидову плоскость E_2 . Если ψ — путь, $z \in E_2$ и $r > 0$, α — действительные числа, то обозначим через $\mu_r^\psi(\alpha; z)$ ($0 \leq \mu_r^\psi(\alpha; z) \leq +\infty$) число точек, в которых ψ пересекается с открытым отрезком $\{\zeta; \zeta = z + \varrho \exp i\alpha, 0 < \varrho < r\} = S_r^\alpha(z)$. Так как функция $\mu_r^\psi(\alpha; z)$ переменного α измерима (по Лебегу), то можно палагать по определению $v_r^\psi(z) = \int_0^{2\pi} \mu_r^\psi(\alpha; z) d\alpha$. Аналогично обозначим через $v^\psi(\varrho; z)$ число пересечений ψ с окружностью $\{\zeta; |\zeta - z| = \varrho\}$ и положим (что возможно вследствие измеримости $v^\psi(\varrho; z)$ относительно переменного ϱ) $u_r^\psi(z) = \int_0^r v^\psi(\varrho; z) d\varrho$. Если ψ не имеет общих точек с множеством $\bigcup_{\alpha} S_{2r}^\alpha(z)$, где $\alpha \in (\beta - \delta, \beta + \delta) \cup (\beta + \pi - \delta, \beta + \pi + \delta)$, $0 < \delta < \pi/2$, то для каждого ϱ , $0 < \varrho < r$, справедливы неравенства

$$\begin{aligned} \varrho^{-1} u_\varrho^\psi(z) &\leq K[v_r^\psi(z) + v_{2\varrho}^\psi(z + \varrho \exp i\beta)], \\ v_r^\psi(z + \varrho \exp i\beta) &\leq M[v_{2r}^\psi(z) + \sup_{0 < x < 2r} x^{-1} u_x^\psi(z)], \end{aligned}$$

где константы K, M зависят только от δ . Эти неравенства находят применение в исследованиях граничного поведения логарифмического потенциала двойного слоя.
