CONTACT BETWEEN ELASTIC BODIES — III. DUAL FINITE ELEMENT ANALYSIS

JAROSLAV HASLINGER, IVAN HLAVÁČEK

(Received August 24, 1979)

In Part I and II of this paper, the primary variational formulation of the contact problem — i.e., in terms of displacements — has been studied. In the present part, we use a dual variational formulation of the same problem, — i.e., in terms of stresses. For simplicity, we restrict ourselves to the problems with a bounded contact zone and with polygonal boundaries.

The dual formulation — i.e. principle of minimum complementary energy is deduced in Section 1 via the theory of a saddle-point. In contradistinction to the primary principle — i.e. minimum of potential energy — we obtain a uniquely solvable formulation even in case that the primary formulation has an infinity of solutions.

In section 2 we define approximations to the dual variational problem on the basis of self-equilibrated triangular block-elements, which have been proposed by Watwood and Hartz [3] and studied in [4] and [5]. An a priori $L_2$-error estimate is proved under a hypothesis that the solution is sufficiently regular. An algorithm for the approximations is presented in Section 3.

I. DUAL VARIATIONAL FORMULATION OF THE CONTACT PROBLEM WITH A BOUNDED CONTACT ZONE AND ZERO FRICTION

Starting with the primary variational formulation — the principle of minimum potential energy — we derive a dual formulation — the principle of minimum complementary energy — via theory of a saddle-point. To this end, we recall first the concept of the saddle-point.

Let $\mathcal{A}, \mathcal{B}$ be two non-empty sets, $\mathcal{H}$ a real functional, defined on $\mathcal{A} \times \mathcal{B}$. The pair $\{ u, \lambda \}$ will be called a saddle point of $\mathcal{H}$ on $\mathcal{A} \times \mathcal{B}$, if

\begin{equation}
\mathcal{H}(u, \mu) \leq \mathcal{H}(u, \lambda) \leq \mathcal{H}(v, \lambda) \quad \forall v \in \mathcal{A}, \quad \forall \mu \in \mathcal{B}.
\end{equation}
Lemma 1.1. Let \( \{u, \lambda\} \) be a saddle point of \( \mathcal{H} \) on \( \mathcal{A} \times \mathcal{B} \). Then
\[
\mathcal{H}(u, \lambda) = \inf_{v \in \mathcal{V}} \sup_{\mu \in \mathcal{B}} \mathcal{H}(v, \mu) = \sup_{v \in \mathcal{V}} \inf_{\mu \in \mathcal{B}} \mathcal{H}(v, \mu).
\]

For the proof — see e.g. [2] — chpt. 5.

Let us recall the primary variational formulation of the contact problem (cf. [1] — Section 1). We introduced the following notation
\[
W = \{u \mid u = (u', u'') \in [H^1(\Omega')]^2 \times [H^1(\Omega'')]^2\},
\]
\[
V = \{v \in \mathcal{V} \mid \text{on } \Gamma_1, u'' = 0 \text{ on } \Gamma_2\},
\]
\[
K = \{v \in V \mid v' + v'' \leq 0 \text{ on } \Gamma_1\},
\]
\[
A(u, v) = \int_{\Omega \cup \Omega'} c_{ijkl} e_{ij}(u) e_{lm}(v) \, dx,
\]
\[
L(v) = \int_{\Omega \cup \Omega'} F_i v_i \, dx + \int_{\Gamma_1 \cup \Gamma_2} P_i v_i \, ds,
\]
\[
\mathcal{L}(v) = \frac{1}{2} A(v, v) - L(v).
\]

The primary problem is to find \( u \in K \) such that
\[
(1.2) \quad \mathcal{L}(u) \leq \mathcal{L}(v) \quad \forall v \in K.
\]

Let us introduce a set \( S \) of new parameters as follows:
\[
S = \{N = (N_{ij}); i, j = 1, 2, N_{ij} \in L^2(\Omega), N_{12} = N_{21}\}, \quad \Omega = \Omega' \cup \Omega''.
\]

Setting
\[
(1.3) \quad N_{ij} = e_{ij}(v), \quad i, j = 1, 2,
\]
we may write
\[
\mathcal{L}(v) = \frac{1}{2} \int_\Omega c_{ijkl} N_{ij} N_{kl} \, dx - L(v) = \mathcal{L}_1(N, v)
\]
and the primary problem (1.2) is equivalent to the minimization of \( \mathcal{L}_1(N, v) \) with the constraints (1.3). The latter problem can be solved by means of Lagrange multipliers \( \lambda \) and the following Lagrangian \( \mathcal{L} \):
\[
\mathcal{L}([N, v], \lambda) = \mathcal{L}_1(N, v) + \int_\Omega \lambda_i (e_{ij}(v) - N_{ij}) \, dx.
\]

It is readily seen that
\[
\sup_{\lambda \in S} \int_\Omega \lambda_i (e_{ij}(v) - N_{ij}) \, dx = \begin{cases} 0 & \text{if } N_{ij} = e_{ij}(v) \quad \forall i, j \vspace{1em} \text{if not.} \end{cases}
\]
Consequently, any solution $u$ of the primary problem (1.2) satisfies the relation

\[(1.4) \quad \mathcal{L}(u) = \inf_{v \in K} \mathcal{L}(v) = \inf_{v \in K} \sup_{\lambda \in S} \mathcal{K}([N, v], \lambda) . \]

The following variational problem

\[(1.5) \quad \sup_{\lambda \in S} \inf_{[N, v] \in S \times K} \mathcal{K}([N, v], \lambda) \]

is called dual to the (primary) problem (1.4). It is desirable to investigate the relation between the values of (1.4) and (1.5). To this end we apply lemma 1. We first prove

**Lemma 1.2.** Let $[[N^*, v^*], \lambda^*]$ be a saddle point of $\mathcal{K}$ on $W \times S$, where $W = S \times K$. Then a solution $u$ of the primary problem exists and

$[N^* = e(u), \quad v^* = u, \quad \lambda^* = \tau(u), \]

where $e(u)$ and $\tau(u)$ are the corresponding strain and stress tensor, respectively.

**Proof.** From (1.1) we deduce:

\[(1.6) \quad \delta_\lambda \mathcal{K}([N^*, v^*], \lambda^*) = 0 \Leftrightarrow N_{ij}^* = e_{ij}(v^*), \]
\[(1.7) \quad \delta_\lambda \mathcal{K}([N^*, v^*], \lambda^*) = 0 \Leftrightarrow \lambda_{ij}^* = c_{ijkl}N_{kl}^*, \]
\[(1.8) \quad \delta_\lambda \mathcal{K}([N^*, v^*], \lambda^*)(v - v^*) \geq 0 \quad \forall v \in K \]

(\text{where e.g. } \delta_\lambda \mathcal{K} \text{ denotes the partial Gâteaux derivative of } \mathcal{K} \text{ with respect to } \lambda). 

The inequality (1.8) together with (1.6) and (1.7) implies

\[A(v^*, v - v^*) \geq L(v - v^*) \quad \forall v \in K . \]

Consequently, $v^*$ is a solution of the problem (1.2).

**Lemma 1.3.** Let $u$ be a solution of the primary problem. Then $[[e(u), u], \tau(u)]$ is a saddle point of $\mathcal{K}$ on $W \times S$.

**Proof.** We have to verify that

\[\mathcal{K}([[e(u), u], \mu]) \leq \mathcal{K}([[e(u), u], \tau(u)]) \leq \mathcal{K}([[N, v], \tau(u))] \]

holds for any $\mu \in S$ and $[[N, v]] \in W$.

The left-hand inequality turns to an equality due to the definition of $\mathcal{K}$. The right-hand inequality can be written in the following form

\[\frac{1}{2} \int_\Omega c_{ijkl} e_{ij}(u) e_{kl}(u) \, dx - L(u) \leq \]
\[\leq \frac{1}{2} \int_\Omega c_{ijkl} N_{ij} N_{kl} \, dx - L(v) + \int_\Omega c_{ijkl} e_{kl}(u) (e_{ij}(v) - N_{ij}) \, dx , \]

323
which is equivalent to
\[
\frac{1}{2} \int_{\Omega} c_{ijkl}(N_{ij} - e_{ij}(u)) (N_{kl} - e_{kl}(u)) \, dx + \\
+ \int_{\Omega} c_{ijkl} e_{ij}(u) e_{ij}(v - u) \, dx \geq L(v - u) \quad \forall v \in K, \quad \forall N \in \mathcal{S}.
\]

The latter inequality, however, is an easy consequence of the ellipticity of the coefficients \(c_{ijkl}\) (cf. (1.4) in [1] — 1) and the definition of \(u\).

**Lemma 1.4.** Let a solution \(u\) of the primary problem (1.2) exist. Then
\[
\mathcal{L}(u) = \inf_{\lambda \in \mathcal{S}} \sup_{v \in \mathcal{K}} \mathcal{H}(N, v, \lambda) = \sup_{\lambda \in \mathcal{S}} \inf_{v \in \mathcal{K}} \mathcal{H}(N, v, \lambda).
\]

**Proof.** Using (1.4), Lemma 1.3 and Lemma 1.1, the assertion follows.

Next let us simplify the dual problem (1.5) by an elimination of the variables \([N, v]\). Consider the „inner” problem
\[
\inf_{[N, v] \in \mathcal{W}} \mathcal{H}(N, v, \lambda),
\]
where \(\lambda \in \mathcal{S}\) is a fixed element. Obviously, we have
\[
(1.10) \quad \inf_{\mathcal{W}} \mathcal{H} = \inf_{\lambda \in \mathcal{S}} \mathcal{H}_1(N, \lambda) + \inf_{v \in \mathcal{K}} \mathcal{H}_2(v, \lambda)
\]
where
\[
\mathcal{H}_1(N, \lambda) = \frac{1}{2} \int_{\Omega} c_{ijkl} N_{ij} N_{kl} \, dx - \int_{\Omega} \lambda_{ij} N_{ij} \, dx,
\]
\[
(1.11) \quad \mathcal{H}_2(v, \lambda) = \int_{\Omega} \lambda_{ij} e_{ij}(v) \, dx - L(v).
\]

We can find easily that
\[
(1.12) \quad \inf_{\lambda \in \mathcal{S}} \mathcal{H}_1(N, \lambda) = \mathcal{H}_1(N^*, \lambda) = -\frac{1}{2} \int_{\Omega} a_{ijkl} \lambda_{ij} \lambda_{kl} \, dx,
\]
where \(a_{ijkl}\) are coefficients of the inverse generalized Hooke’s law and \(N^*_{ij} = a_{ijkl} \lambda_{ij} \lambda_{kl}\).

Let there exist a \(v_0 \in \mathcal{K}\) such that \(\mathcal{H}_2(v_0, \lambda) < 0\). Since \(\mathcal{K}\) is a convex cone, \(tv_0 \in \mathcal{K}\) and
\[
\mathcal{H}_2(tv_0, \lambda) \rightarrow -\infty \quad \text{for} \quad t \rightarrow +\infty.
\]

If \(\mathcal{H}_2(v, \lambda) \geq 0\) for all \(v \in \mathcal{K}\), then
\[
\inf_{v \in \mathcal{K}} \mathcal{H}_2(v, \lambda) = \mathcal{H}_2(0, \lambda) = 0.
\]

Denote
\[
(1.13) \quad K^+_p = \{\lambda \in \mathcal{S} \mid \mathcal{H}_2(v, \lambda) \geq 0 \ \forall v \in \mathcal{K}\}.
\]
We thus obtained that

\[(1.14) \quad \inf_{\nu \in K} H'_2(\nu, \lambda) = \begin{cases} 0 & \text{if } \lambda \in K'_{F,P}, \\ -\infty & \text{if } \lambda \notin K'_{F,P}. \end{cases} \]

**Lemma 1.5.** Let a solution \( u \) of the primary problem exist. Then \( K'_{F,P} \) is a non-empty, closed and convex subset of \( S \).

**Proof.** We show that \( \tau(\nu) \) belongs to \( K'_{F,P} \). In fact,

\[\int_\Omega \tau_{ij}(\nu) e_{ij}(\nu - u) \, dx \geq L(\nu - u) \quad \forall \nu \in K\]

holds and substituting \( \nu = u + w \), where \( w \) is any element of \( K \), we obtain

\[H'_2(w, \tau(u)) = \int_\Omega \tau_{ij}(\nu) e_{ij}(\nu) - L(w) \geq 0 \quad \forall w \in K.\]

The convexity and closedness of \( K'_{F,P} \) is easy to see.

From \((1.10), (1.12) \) and \((1.14) \) it follows that

\[\inf_{[\nu, \nu'] \in \mathcal{W}} H'(\nu', \nu, \lambda) = \begin{cases} -\mathcal{J}(\lambda) & \text{if } \lambda \in K'_{F,P}, \\ -\infty & \text{if } \lambda \notin K'_{F,P}. \end{cases} \]

where

\[\mathcal{J}(\lambda) = \frac{1}{2} \int_\Omega a_{ijk} \lambda_{ij} \lambda_{kl} \, dx.\]

Consequently, we have

\[\sup_{\lambda \in S} \inf_{[\nu, \nu'] \in \mathcal{W}} H'(\nu', \nu, \lambda) = \sup_{\lambda \in K'_{F,P}^+} (-\mathcal{J}(\lambda)) = -\inf_{\lambda \in K'_{F,P}} \mathcal{J}(\lambda).\]

Moreover, if a saddle point of \( H' \) on \( \mathcal{W} \times S \) exists, then

\[(1.15) \quad -\inf_{\lambda \in K'_{F,P}^+} \mathcal{J}(\lambda) = -\mathcal{J}(\tau(u)) = \mathcal{J}(u),\]

where \( u \) is a solution to the primary problem. In fact, the assertion follows from Lemmas 1.2, 1.1 and 1.4.

On the other hand, Lemma 1.3 guarantees the existence of a saddle point, provided a solution of the primary problem exists.

In [1] — I, Section 2, we studied the existence and uniqueness of weak solutions of the primary problem \( \mathcal{P}_1 \), i.e., \((1.2) \). Under the assumptions of Theorem 2.2 there, i.e. if

\[(1.16) \quad L(y) \leq 0 \quad \forall y \in K \cap \mathcal{R}, \]

\[L(y) < 0 \quad \forall y \in K \cap \mathcal{R} \setminus \mathcal{R}^*, \]

325
a solution \( u \) of the primary problem exists. Since the difference of any two solutions belongs to the subspace \( \mathcal{R} \) of rigid displacements, both \( e(u) \) and \( \tau(u) \) are determined uniquely. Consequently, if (1.16) holds, the saddle point of \( \mathcal{H} \) exists, its last component is uniquely determined and (1.15) is true. In other words, the dual problem to find \( \lambda \in K_{F,P}^+ \) such that

\[
\mathcal{S}(\lambda) \leq \mathcal{S}(\mu), \quad \forall \mu \in K_{F,P}^+, \quad (1.17)
\]

has a unique solution \( \lambda = \tau(u) \), where \( u \) is any solution of the primary problem.

Thus we obtained a uniquely solvable formulation of a general class of contact problems in contradistinction to the primary variational formulation (see Section 2 of [1] — I, where only the cases of one-dimensional spaces of rigid virtual displacements have been considered).

Remark 1.1. The existence and uniqueness of the solution of (1.17) can be proved directly, using Lemma 1.5 and the strict convexity of the functional \( \mathcal{S} \).

Remark 1.2. Let us emphasize that the dual problem is uniquely solvable, whenever the primary problem possesses a solution. The existence (and uniqueness) of the solution for the dual problem, however, follows directly, if the set \( K_{F,P}^+ \) is non-empty. Thus a possibility arises that the dual problem may have a solution even in some cases when the primary problem has not. We shall not investigate the latter question, but remark only that the set \( K_{F,P}^+ \) is non-empty only if the condition (1.16) is satisfied. Consequently, (1.16) is a necessary condition for the existence of a solution for both the primary and the dual problem.

Interpretation of the set \( K_{F,P}^+ \)

For the purposes of an approximation, it is useful to study the set \( K_{F,P}^+ \) of admissible stress fields more closely.

Lemma 1.6. 1° Let \( \lambda \in K_{F,P}^+ \) be sufficiently smooth. Then \( \lambda \) satisfies the following conditions:

\[
\frac{\partial \lambda_{ij}}{\partial x_j} + F_i = 0 \quad \text{in} \quad \Omega = \Omega' \cup \Omega'' , \quad i = 1, 2 , \quad (1.18)
\]

\[
\lambda_{ij} n_j = P_i \quad \text{on} \quad \Gamma_t = \Gamma'_t \cup \Gamma''_t , \quad i = 1, 2 , \quad (1.19)
\]

\[
T_t(\lambda) = 0 \quad \text{on} \quad \Gamma_0 , \quad (1.20)
\]

\[
T_t(\lambda') = T_t(\lambda'') = 0 \quad \text{on} \quad \Gamma_K , \quad (1.21)
\]

\[
T_n(\lambda') = T_n(\lambda'') \leq 0 \quad \text{on} \quad \Gamma_K . \quad (1.22)
\]

2° Conversely, let \( \lambda \in S \) be sufficiently smooth and let it satisfy (1.18) — (1.22). Then \( \lambda \in K_{F,P}^+ \).
Proof. 1° Integrating by parts we obtain for any \( v \in K \)
\[
\int_{\Omega} \lambda_{ij} e_{ij}(v) \, d\mathbf{x} = -\int_{\Omega} v_i \frac{\partial \lambda_{ij}}{\partial x_j} + \int_{\partial \Omega \cup \partial \Omega^*} (T_n(\lambda) v_n + T_i(\lambda) v_i) \, ds \geq \int_{\Omega} F_i v_i \, d\mathbf{x} + \int_{\Gamma_e} P_i v_i \, ds.
\]

Inserting \( v_i^M = \pm \phi_1 \in C_0^\infty(\Omega^M), \, M = \,' \), we are led to (1.18). Hence we obtain
\[
\int_{\partial \Omega \cup \partial \Omega^*} T_i(\lambda) v_i \, ds \geq \int_{\Gamma_e} P_i v_i \, ds \quad \forall v \in K.
\]

Choosing \( v_i = \pm \psi_i \) such that the traces of \( \psi \) have their support in \( \Gamma_e \), we obtain (1.19).

Let us choose \( v' = 0, \, v'' \) with \( v''_i = 0, \, v''_n = \pm \psi \) on \( \Gamma_0 \), where the support of \( \psi \) is in \( \Gamma_0 \). Consequently, (1.20) follows.

It remains to analyze the inequality
\[
(1.23) \quad \int_{\Gamma_K} (T_n(\lambda') v'_n + T_i(\lambda') v'_i + T_n(\lambda'') v''_n + T_i(\lambda'') v''_i) \, ds \geq 0 \quad \forall v \in K.
\]

Choosing \( v \in V \) such that \( v'_i = v''_i = 0 \) and \( v''_n = -v'_n = \pm \varphi \) on \( \Gamma_K \), \( \varphi \in C_0^\infty(\Gamma_K) \), we obtain
\[
\int_{\Gamma_K} (T_n(\lambda') - T_n(\lambda'')) \varphi \, ds = 0.
\]

Hence
\[
T_n(\lambda') = T_n(\lambda'') \quad \text{on} \quad \Gamma_K.
\]

Let us choose \( v \in V \) such that \( v'_n = v''_n = 0, \, v''_i = 0, \, v'_i = \pm \varphi \) on \( \Gamma_K \). Then (1.23) yields \( T_i(\lambda') = 0 \) on \( \Gamma_K \). The condition \( T_i(\lambda'') = 0 \) can be derived in a similar way.

It remains
\[
\int_{\Gamma_K} T_n(\lambda) (v'_n + v''_n) \, ds \geq 0 \quad \forall v \in K
\]
and \( T_n(\lambda) \leq 0 \) follows, using the condition \( v'_n + v''_n \leq 0 \) on \( \Gamma_K \).

2° Let us multiply (1.18) by a function \( v_i \), where \( v \in K \), and integrate over \( \Omega \) by parts. We obtain
\[
0 = -\int_{\Omega} \lambda_{ij} \frac{\partial v_i}{\partial x_j} \, d\mathbf{x} + \int_{\Omega} F_i v_i \, d\mathbf{x} + \int_{\partial \Omega \cup \partial \Omega^*} \lambda_{ij} n_j v_i \, ds =
\]
\[
= -\int_{\Omega} \lambda_{ij} e_{ij}(v) \, d\mathbf{x} + L(v) + \int_{\Gamma_K} T_n(\lambda) (v'_n + v''_n) \, ds
\]
From the definition of \( K \) and (1.22) we conclude that the last integral is non-negative and consequently, \( \lambda \in K_{F,p}^+ \).

327
2. APPROXIMATIONS OF THE DUAL PROBLEM WITH A BOUNDED CONTACT ZONE

As usually, finite-dimensional approximations of the set $K_{F,P}^+$ of admissible stress-functions are needed. To this end, it is suitable first to find a "particular" solution $\bar{\lambda}$ of the non-homogeneous conditions (1.18), (1.19) and then to write

$$\lambda = \bar{\lambda} + \tau,$$

where $\tau$ are self-equilibrated stress fields.

Since the system of forces $F_i, P_i$ acting on $\Omega''$ has a non-zero resultant, it is necessary to introduce reaction forces (normal vector loading) on $\Gamma_K$, with respect to both $\Omega''$ and $\Omega'$.

Lemma 2.1. If $\bar{\lambda} \in S$ satisfies (1.18), (1.19), then

$$\int_{r_K} T_i(\bar{\lambda}) \, ds = -\left(\int_{\Gamma} F_i \, d\mathbf{x} + \int_{r''} P_i \, ds + \int_{r_0} T_i(\bar{\lambda}) \, ds\right), \quad i = 1, 2.$$  

Proof. Using (1.18) and (1.19), we may write

$$-\int_{\Omega''} F_i \, d\mathbf{x} = \int_{\Omega''} \frac{\partial \bar{\lambda}_J}{\partial x_J} \, d\mathbf{x} = \int_{\Omega''} \bar{\lambda}_J n_J \, ds = \int_{r''} P_i \, ds + \int_{r_0} T_i(\bar{\lambda}) \, ds + \int_{r_K} T_i(\bar{\lambda}) \, ds,$$

and (2.1) follows. Q.E.D.

Observing Lemma 2.1, we can choose a simplest distribution of the reaction forces $T_i(\bar{\lambda})$ on $\Gamma_K$.

Example 1. Let $\Gamma_0$ consist of straight segments parallel with $x_1$-axis and $\Gamma_K$ be a straight segment such that $n_1' > 0$ on $\Gamma_K$. We can choose $\bar{\lambda} \in K_{F,P}^+$ such that

$$T_i(\bar{\lambda}) = T_i(\bar{\lambda}) = g \quad \text{on} \quad \Gamma_K,$$

where

$$g = -\left(\int_{\Omega''} F_1 \, d\mathbf{x} + \int_{r''} P_1 \, ds\right)/\int_{\Gamma_K} d\mathbf{x} = \text{const}.$$  

In fact, using $T_i(\bar{\lambda}) = T_i(\bar{\lambda}) = 0$ on $\Gamma_0$ and $d\mathbf{x} = n_1' \, ds$, $T_i(\bar{\lambda}) = 0$ on $\Gamma_K$, we realize that the choice (2.2), (2.3) satisfies the necessary equilibrium conditions (2.1). Moreover, the necessary condition for the existence of a solution is

$$V_1 = \int_{\Omega''} F_1 \, d\mathbf{x} + \int_{r''} P_1 \, ds \geq 0$$

(cf. Remark 1.2 and (1.16)$_1$). Hence $g \leq 0$ and (1.22) is also true.
Example 2. For the same $\Gamma_0$ and $\Gamma_K$ with $n''_2 > 0$ on $\Gamma_K$, we choose (2.2) with $g = 0$ and

$$T_i(\lambda') = T_i(\lambda'') = g_1 = -V_1 \int_{\Gamma_K} d\lambda = 0$$

Obviously, $\lambda \notin K_{F,p}$, unless $V_1 = 0$.

Example 3. Let $\Gamma_0 = \emptyset$ and $\Gamma_K$ be a straight segment parallel with $x_1$-axis. We can choose $\lambda$ such that

$$T_n(\lambda') = -T_n(\lambda'') = V_2 \int_{\Gamma_K} ds = g$$

where $V_2 = \int_{\Omega} F_2 \, d\lambda + \int_{\Gamma} P_2 \, ds$. Since $V_2 \leq 0$ is necessary for the existence of a solution, we have $T_n(\lambda') \leq 0$ on $\Gamma_K$ and (1.22) can also be satisfied.

Remark 2.1. It is not essential for $\lambda$ to belong to $K_{F,p}$. From the practical point of view, however, $\lambda$ should be such that $T_i(\lambda)$ are constant on $\Gamma_K$. Then we can construct internal approximations of $K_{F,p}$, which is advantageous.

Remark 2.2. An algorithm for finding $\lambda$ will be considered in Section 3.

Henceforth we choose the configuration of Example 1 to show the approximations of $K_{F,p}$ in detail. Let the stress field $\lambda$ satisfy the following condition

$$\int_\Omega \lambda_{ij} e_{ij}(\nu) \, d\lambda = L(\nu) + \int_{\Gamma_K} g(v'_n + v''_n) \, ds \quad \forall \nu \in V.$$ 

Obviously, it holds

$$\lambda \in K_{F,p} \Leftrightarrow \lambda - \bar{\lambda} = \tau \in \mathcal{U}_0,$$

where

$$\mathcal{U}_0 = \left\{ \tau \in S \left| \int_\Omega \tau_{ij} e_{ij}(\nu) \, d\lambda \geq -g \int_{\Gamma_K} (v'_n + v''_n) \, ds \quad \forall \nu \in K \right. \right\}.$$

Lemma 2.2. 1° Let $\tau \in \mathcal{U}_0$ be sufficiently smooth. Then $\tau$ satisfies homogeneous equations (1.18), (1.19), (1.20), (1.21) and

$$T_n(\tau') = T_n(\tau'') \leq -g \quad \text{on} \quad \Gamma_K.$$

2° Let $\Omega$ be divided into a finite number of closed subdomains $K_r$,

$$\Omega = \bigcup_r K_r, \quad \bar{K}_r \cap \bar{K}_s = \emptyset \quad \text{if} \quad r \neq s.$$ 

Let $\tau \in S$ satisfy the homogeneous equations (1.18) in every $K_r$, homogeneous boundary conditions (1.19), (1.20), (1.21) and (2.8). Moreover, let the stress vector $T(\tau)$ be continuous across any common boundary of two adjoint subdomains, i.e. $T(\tau)|_{K_r} + T(\tau)|_{K_s} = 0$ on $K_r \cap K_s, \forall r \neq s$.

Then $\tau \in \mathcal{U}_0$.

Proof is analogous to that of Lemma 1.6.
Remark 2.3. If the condition (2.4) holds, \( \mathcal{W}_0 \) is non-empty, since it contains the zero element. Moreover, \( \mathcal{W}_0 \) is convex and closed subset of \( S \).

Substituting \( \lambda = \bar{\lambda} + \tau \) into the definition (1.17) of the dual problem, we obtain an equivalent dual problem: to find \( \tau^0 \in \mathcal{W}_0 \) such that

\[
J(\tau^0) \leq J(\tau) \quad \forall \tau \in \mathcal{W}_0 ,
\]

where

\[
J(\tau) = \frac{1}{2} \int_\Omega a_{ijkl} \tau_{ij}(\tau_{kl} + 2\lambda_{kl}) \, dx .
\]

2.1. AN EQUILIBRIUM FINITE ELEMENT MODEL

Since the admissible stress functions in the equivalent dual problem (2.9) have to satisfy the homogeneous equations (1.18) of equilibrium, we need some finite-dimensional subspaces with the same property. To this end, we can employ an equilibrium stress field model proposed by Watwood and Hartz [3].

The model consists of triangular block-elements, each of them being generated by connecting the vertices of a general triangle with its centre of gravity. On each subtriangle 3 linear functions — components of a self-equilibrated stress field are defined. The stress vector has to be continuous when crossing any common boundary of two subtriangles.

For an arbitrary triangle \( K \) let us define the space of self-equilibrated linear stress fields as follows

\[
M(K) = \{ \tau_{11} = \beta_1 + \beta_2 x_1 + \beta_3 x_2, \tau_{22} = \beta_4 + \beta_5 x_1 + \beta_6 x_2, \tau_{12} = \tau_{21} = \beta_7 - \beta_6 x_1 - \beta_2 x_2 \} ,
\]

where \( \beta \in \mathbb{R}^7 \) is an arbitrary vector. It is readily seen that \( \partial \tau_{ij} / \partial x_j = 0 \) in \( K \) for any \( \tau \in M(K), i = 1, 2 \). Next let us consider a triangular block-element \( K = \bigcup_{i=1}^3 K_i \) (see Fig. 1) and define

\[
N(K) = \{ \tau = (\tau^1, \tau^2, \tau^3) | \tau^i \big|_{K_i} \in M(K_i) ,
T(\tau^i) + T(\tau^{i-1}) = 0 \text{ on } 0a_i, i = 1, 2, 3, \text{ modulo } 3 \} .
\]

The last equations mean that the stress vectors are continuous across any side \( 0a_i \).

Theorem 2.1. Let an arbitrary external loading \( T^0 \) of the triangle \( K \) be given,
such that (i) it varies linearly along the sides of $K$, and (ii) it satisfies the global equilibrium conditions.

Then a unique stress field $\tau \in N(K)$ exists such that

$$T(\tau) = T^0 \quad \text{on} \quad \partial K.$$ 

Moreover the following estimate holds

$$\max_{i=1,2,3} \| T^i \|_{C(K_i)} \leq c(\alpha) \max_{k=1,2} | T^0_k(s) |,$$

where the constant $c(\alpha)$ depends on the minimal angle $\alpha$ of $K$ only.

Let $G$ be a bounded polygonal domain, $h \in (0, 1)$ a parameter, $\mathcal{T}_h$ a triangulation of $G$. Define

$$h = \max_{K \in \mathcal{T}_h} \text{diam} \, K,$$

$$N_h(G) = \{ \tau | \tau |_K \in N(K) \ \forall K \in \mathcal{T}_h, \ T(\tau)|_K + T(\tau)|_K^c = 0 \ \text{on any} \ K \cap \bar{K}^c \},$$

$$E(G) = \{ \tau | \tau \in [H^1(G)]^n, \ \tau_{12} = \tau_{21}, \ \partial \tau_{ij}/\partial x_j = 0 \ \text{in} \ G, \ i = 1, 2 \}.$$ 

**Theorem 2.2.** There exists a linear continuous mapping $r_h : E(G) \to N_h(G)$ such that for any $\tau \in E(G) \cap [H^2(G)]^n$

$$\| \tau - r_h \tau \|_{[L_2(G)]^n} \leq C h^2 \| \tau \|_{[H^2(G)]^n}$$

holds, where $C$ does not depend on $h$ and $\tau$, provided the family $\{ \mathcal{T}_h \}$ of triangulations is regular (cf. [1] — II, Section 2.1).

For the proof — see [4] — Theorem 2.5.

**Remark 2.4.** The estimate (2.11) follows also from some results of Johnson and Mercier [5].

The mapping $r_h$ from Theorem 2.2 is defined “locally” on every triangular block-element $K \in \mathcal{T}_h$ as follows:

The stress vector components $T_i(\tau)$ on any side $S_j$ of $K$ are projected in $L_2(S_j)$ onto the space $P_1(S_j)$ of linear functions. By these projections $T^0$, the stress field $r_h \tau |_K \in N(K)$ is determined uniquely, by virtue of Theorem 2.1.

**Remark 2.5.** Any stress field $\tau \in N_h(G)$ satisfies the equilibrium equations $\partial \tau_{ij}/\partial x_j = 0, \ i = 1, 2$ in the sense of distributions.

### 2.2. Approximations of the Dual Problem by an Equilibrium Finite Element Model

Assume that both $\Omega'$ and $\Omega''$ are bounded polygonal domains. We define an approximation of $\mathcal{V}_0$ as follows:

$$\mathcal{V}_0 = \mathcal{V}_0 \cap N_h(\Omega),$$
where
\[ N_h(\Omega) = \{(\tau', \tau'')| \tau^M \in N_h(\Omega^M), \ M = '\ ', ''\} . \]

We say that \( \tau^h \in \mathcal{U}_oh \) is an approximation of the dual problem, if
\[ (2.12) \quad J(\pi^h) \leq J(\pi) \quad \forall \pi \in \mathcal{U}_oh . \]

**Lemma 2.3.** If (2.4) holds, there exists a unique solution of the problem (2.12).

**Proof.** Obviously, \( N_h(\Omega) \subset S \) is a linear and finite-dimensional subset, therefore it is closed and convex. Using Remark 2.3, we conclude that also \( \mathcal{U}_oh \) is closed, convex and non-empty. Since the functional \( J \) is differentiable and strictly convex, the existence and uniqueness of \( \tau^h \) follows easily.

An algorithm for finding \( \tau^h \) will be presented in the next Section. Here we shall try to estimate the error
\[ \|\lambda - \lambda^h\|_{0, \Omega} = \|\tau^0 - \tau^h\|_{0, \Omega} \]
where
\[ \lambda = \tilde{\lambda} + \tau^0, \quad \lambda^h = \tilde{\lambda} + \tau^h, \quad \|\cdot\|_{0, \Omega} = \|\cdot\|_{L^2(\Omega)} . \]

To this end we employ a lemma of Mosco and Strang [6].

**Lemma 2.4.** Let an element \( W^h \in \mathcal{U}_oh \) exist such that
\[ (2.13) \quad 2\tau^0 - W^h \in \mathcal{U}_o . \]
Then it holds
\[ (2.14) \quad \|\tau^0 - \tau^h\|_{0, \Omega} \leq C\|\tau^0 - W^h\|_{0, \Omega} . \]

Hence it remains to construct a \( W^h \in \mathcal{U}_oh \), satisfying (2.13) and sufficiently close to \( \tau^0 \).

**Theorem 2.3.** Let \( \Gamma_0 \) consist of straight segments parallel with \( x_1 \)-axis and \( \Gamma_K \) be a straight segment such that \( n_1^0 > 0 \) on \( \Gamma_K \).

Assume that \( \tau^0|_{\Gamma_M \in [H^2(\Omega^M)]^2}, \ M = ' , \|, \) and \( T_\epsilon(\tau^0) \in H^2(\Gamma_K) \). Let the family of triangulations \( \{\mathcal{T}_h\}, \ 0 < h \leq 1 \), satisfy the following conditions:

(A1) it is regular (cf. [1] — II, Section 2.1);

(A2) a positive number \( \beta \) exists, independent of \( h \) and such that the ratio of any two sides in \( \mathcal{T}_h \) is less than \( \beta \);

(A3) between \( \Gamma_K \) and \( \Gamma_0 \) in \( \Omega^\prime \) and between \( \Gamma_K \) and \( \Gamma_\epsilon \) in \( \Omega \) the triangulation \( \mathcal{T}_h \) is inscribed into smooth "vaulted strips" with bounded curvature and bounded slope \( |\theta| \leq \Theta < \pi/2 \), (\( \Theta \) independent of \( h \)), which are perpendicular to \( \Gamma_0 \) and \( \Gamma_K \) — see Fig. 2.
Then
\[ \| \tau^0 - \tau^h \|_{0, \Omega} \leq C(\tau^0) h^{3/2}, \]
where \( C(\tau^0) \) does not depend on \( h \).

**Proof** is based on Lemma 2.4 and the two following lemmas.

**Lemma 2.5.** Assume that \( \tau^0 \in H^2(\Omega^M) \), \( M = 1 \), \( \| \), \( T_h(\tau^0) \in H^2(\Gamma_K) \). Then a piecewise linear function \( \psi^h \) on \( \Gamma_K \) exists with the nodes determined by the triangulation \( S_h \) (discontinuous, in general) and such that
\[
\int_{\Gamma_K} \psi^h \, ds = \int_{\Gamma_K} T_n(r_h \tau^0) \, ds,
\]
\[
2 \, T_n(\tau^0) + g \leq \psi^h \leq -g \text{ on } \Gamma_K,
\]
\[
\| T_n(r_h \tau^0) - \psi^h \|_{0, \Gamma_K} \leq C \, h^2 \left( \frac{\| d^2 }{ds^2 T_n(\tau^0) \|_{0, \Gamma_K} } \right),
\]
where \( r_h \) is the mapping from Theorem 2.2.

**Proof** is analogous to that of Lemma 4.2 in [8].

**Lemma 2.6.** Let the triangulations \( S_h \) satisfy conditions (A1), (A2), (A3). Given a piecewise linear function \( \phi^h \) on \( \Gamma_K \), with the nodes determined by \( S_h \) and such that
\[
(2.15) \quad \int_{\Gamma_K} \phi^h \, ds = 0.
\]

Then there exists a function \( w^h \in N_h(\Omega) \) such that
\[
(2.16) \quad T(w^h) = 0 \text{ on } \Gamma_1,
\]
\[
(2.17) \quad T_i(w^h) = 0 \text{ on } \Gamma_0,
\]
\[
(2.18) \quad T_i(w^h) = T_i(w^h) = 0 \text{ on } \Gamma_K,
\]
\[
(2.19) \quad T_n(w^h) = T_n(w^h) = \phi^h \text{ on } \Gamma_K,
\]
\[
(2.20) \quad \| w^h \|_{0, \Omega} \leq C \, h^{-1/2} \| \phi^h \|_{0, \Gamma_K}.
\]
Proof. Consider e.g. the domain $\Omega'$ and the triangulation $\mathcal{T}_n$, satisfying (A1) – (A3) – see Fig. 2, where $\Gamma_k = AU, \Gamma_0 \supset DV$.

1° Let $ABCD$ be the upper “vaulted strip”. On the edge $AB$ we have a force

$$P_1 = \int_A^B \varphi \, ds$$

(henceforth the superscript $h$ will be omitted), perpendicular to $AB$, acting in $AB$ and a moment $M_1$, where

$$(2.21) \quad |M_1| = \frac{1}{3} l_{AB}^2 \frac{\left| \varphi(A) \right|^2}{\left| \varphi(A) \right| + \left| \varphi(B) \right|}$$

holds if $\varphi(A) < 0, \varphi(B) > 0, |\varphi(A)| \leq |\varphi(B)|$ or $M_1 = 0$ if $\varphi(A) \varphi(B) \geq 0$.

The stress field response to the loading $P_1$ and $M_1$ will be estimated separately.

2° The loading by the force $P_1$. Let the stress vectors on the upper edge $AE_1F_1$ ... of the strip be zero (Fig. 3). On the lower edge $BEF$ ..., however, let a piecewise constant loading $q_i$ acts, parallel to the $x_2$-axis, and such that the resultants $V_j = P_1 - \sum_{i=1}^j q_i l_i e_2, j = 1, 2, \ldots$, are parallel to the tangent $t$ of the arc $AD$ at the points $E_1, F_1, \ldots$, and act inside the sides $E_1E, F_1F, \ldots$.

![Fig. 3](image-url)

We can show that all stress vector components in the strip $ABCD$ are bounded above by the number

$$C \max_{r_k} |\varphi|,$$

where $C$ is independent of $h$.

In fact, we may write (see Fig. 4)

$$(2.22) \quad |P_1| = \frac{1}{2} s_1 |\varphi(A) + \varphi(B)| \leq s_1 \max_{AB} |\varphi|,$$

$$\left| V_i \right| = \left| P_1 \right| \cos \theta_0 \cos^{-1} \theta_1 \leq \left| P_1 \right| \cos^{-1} \Theta$$

$$\left| Q_1 \right| = q_1 l_1 = \left| P_1 \right| \cos \theta_0 (\tan \theta_0 - \tan \theta_1) =$$

$$= \left| P_1 \right| \cos^{-1} \theta_1 \cdot \sin (\theta_0 - \theta_1) \leq$$

$$\leq \left| P_1 \right| \cos^{-1} \Theta \cdot l_1 q^{-1} \leq C \beta \left| P_1 \right| \cdot l_1,$$

where $q$ denotes the radius of the curvature at the point $E_1$. 334
Consequently, we have

\[
|q_1| \leq C \beta |P_1| = C_1 h \max_{AB} \phi.
\]

The values of \(V_i, q_i, i = 2, 3, \ldots\), can be estimated in a similar way.

Next let us consider the stress vectors on the side \(FF_1\). They are equivalent with the resultant \(V_2\), which acts at the point \(F_2, FF_2 = z_0, FF_1 = s_3\) (see Fig. 5). It holds

\[
V_2 = \frac{1}{2} s_3 (\kappa_1 + \kappa)\]

\[
V_2 r_0 = \frac{1}{2} s_3 (\kappa_1 r_1 + \kappa r)
\]

where

\[
r_1 = \frac{3}{2}s_3 \cos \chi, \quad r = \frac{1}{2}s_3 \cos \chi,
\]

\[
r_0 = z_0 \cos \chi, \quad z_0 < s_3.
\]

The solution of (2.24) with respect to \(\kappa_1, \kappa\) yields that

\[
\kappa_1 = \frac{2V_2 (r - r_0)}{s_3 (r - r_1)}.
\]

One easily derives the following inequalities

\[
\frac{|r - r_0|}{r - r_1} = \frac{\frac{3}{2}s_3 - z_0}{\frac{3}{2}s_3} = 1 - 3 \frac{z_0}{s_3} \leq 2,
\]

\[
|\kappa_1| \leq \frac{4}{s_3} |V_2| \leq C \frac{s_1}{s_3} \max_{AB} \phi \leq C \beta \max_{AB} \phi,
\]

where (2.22) has been employed.

A similar estimate can be deduced for \(\kappa\). The stress vectors on the side \(F_1G\) can be estimated by an analogous way.

3° The loading by the moment \(M_1\). From (2.21) it follows

\[
|M_1| \leq \frac{1}{6}s_3^2 \max_{AB} \phi.
\]

Let both the upper and lower edge of the strip \(ABCD\) be without loading. Consider any side connecting the upper with the lower edge, e.g. \(FF_1\). The moment \(M_1\) will be
equivalent with a linear loading, perpendicular to \( FF_T \), the maximal value of which can be estimated as follows

\[
|m| = \frac{6}{s_3^2} |M_1| \leq \left( \frac{s_1}{s_3} \right)^2 \max_{AB} |\varphi| = \beta^2 \max_{AB} |\varphi|.
\]

4° Consider an arbitrary “interior vaulted strip”, between the strips \( ABCD \) and \( TUVZ \) — see Fig. 2. We shall construct the stress vectors, bounded again by \( C \max |\varphi| \).

Let the upper edge be loaded by a piecewise constant load \(-q^H\), acting “upwards” and the lower edge by a piecewise constant load \( q^D \) “downwards”. The differences \( \Delta q_i = q^D_i - q^H_i \) are such that the resultants

\[
V^{(n)}_j = P_n - \sum_{i=1}^{N} \Delta q_i l_i e_2, \quad j = 1, 2, \ldots
\]

where

\[
P_n = \int_{s_1^{(n)}} \varphi \, ds,
\]

are parallel to the corresponding tangent of the upper arc, as previously.

Besides, \( q^H_i \) equals to \( q^D_i \) of the neighbouring strip above, of course.

The resultants \( V^{(n)}_i \) can be estimated as in the strip \( ABCD \). By an analogy to (2.23), we may write

\[
|q^D_i| \leq \sum_{j=1}^{n} |\Delta q^{(j)}_i| \leq \sum_{j=1}^{n} C h \max_{r_K} |\varphi| \leq C_1 \max_{r_K} |\varphi|,
\]

using the inequalities

\[
h \beta \min_{j=1,2,\ldots,n} s_1^{(n)} \leq \beta \sum_{j=1}^{n} s_1^{(n)} \leq \beta \text{mes } \Gamma_K.
\]

5° The loading by the moment \( M_1 \), acting on the interior vaulted strip, can be estimated as that by \( M_1 \) in the upper strip.

6° Finally, let us show that the loading \( q^D_i \) of the lower strip \( TUVZ \) equals to zero if the resultants \( V^{(n)}_i \) are parallel to the same tangent \( t \) at the corresponding vertex of the edge \( AE_1 \ldots D \).

Let \( AU = \Gamma_K \) consist of \( N \) sides \( S_1^{(1)}, \ldots, S_1^{(N)} \). The following equations hold for the quadrangles adjoint to \( \Gamma_K \):

\[
P_1 - \Delta Q^{(1)}_1 e_2 = V^{(1)}_1,
\]

\[
P_2 - \Delta Q^{(2)}_1 e_2 = V^{(2)}_1,
\]

\[
\vdots
\]

\[
P_N - \Delta Q^{(N)}_1 e_2 = V^{(N)}_1,
\]

where \( \Delta Q^{(j)}_1 = Q^{(j)}_1 - Q^{(j-1)}_1, \quad Q^{(j)}_1 = \int_1^{(j)} q^{D(j)}_1, \quad j = 1, 2, \ldots, N. \)
Since (2.15) implies that
\[ \sum_{j=1}^{N} P_j = \int_{\Gamma_K} \varphi \, ds = 0, \]
by adding we obtain
\[ -Q_1^{(N)} e_2 = \sum_{j=1}^{N} V_1^{(j)}. \]

The vectors on both sides have different directions and consequently \( Q_1^{(N)} = 0, \)
\[ \sum_{j=1}^{N} V_1^{(j)} = 0. \]

Considering the second column of quadrangles, we prove that \( Q_2^{(N)} = 0, \) changing
only \( P_j \) for \( V_j, j = 1, 2, \ldots, N, \) a.s.o.

7° The triangulation of \( \Omega^* \) outside the vaulted strip \( AUVD \) can be chosen arbitrar­ily, it must fit in the division of the arcs \( \bar{AD} \) and \( \bar{UV}, \) of course. We choose zero stress field everywhere outside \( AUVD. \)

8° On the domain \( \Omega' \) a parallel approach can be used.

9° The above method of construction of the stress vectors guarantees that each triangular element \( K \) is loaded by self-equilibrated linearly distributed external forces. Theorem 2.1 can be applied to obtain a uniquely determined stress field \( w^h|_K \in N(K) \) and the estimate (2.10) holds. Since the condition of continuity of stress vector is also satisfied, we arrive at a stress field \( w^h \in N_h(\Omega). \) From (2.10) and
the above estimates it follows
\[ \max_{i=1,2,3} \| w^h \|_{c(K_i)} \leq c \max_{r_K} \| \varphi^h \| \quad \forall K \in \mathcal{T}_h, \]
and the same bound is true for \( \| w^h \|_{0, \Omega}. \)

It holds
\[ \max_{r_K} \| \varphi^h \| \leq C h^{-1/2} \| \varphi^h \|_{L^2(r_K)}. \]

In fact, let \( AB \) be an arbitrary side of \( \mathcal{T}_h \) on \( \Gamma_K. \) Then
\[ \int_A \varphi^2 \, ds = \frac{1}{2} l_{AB} \left[ \varphi(A)^2 + \varphi(B)^2 + (\varphi(A) + \varphi(B))^2 \right] \geq \frac{1}{6} l_{AB} \left[ \varphi(A)^2 + \varphi(B)^2 \right], \]
consequently
\[ \varphi(A)^2 + \varphi(B)^2 \leq 6 l_{AB}^{-1} \| \varphi \|_{L^2(\Omega)}^2 \leq 6 \beta h^{-1} \| \varphi \|_{L^2(\Omega)}^2, \]
and (2.26) follows.

Thus we obtain the inequality (2.20). By the construction of \( w^h \) (especially of the stress vector \( T(w^h) \)) it is easy to verify the boundary conditions (2.16)–(2.19).

Q.E.D.

Proof of Theorem 2.3. Let \( \psi^h \) be the function from Lemma 2.5. If we set
\[ \varphi^h = T_h(r_h \tau^0) - \psi^h, \]
then Lemma 2.6 implies that a $w^h \in N_h(\Omega)$ exists, satisfying the boundary conditions (2.16)–(2.19) and the estimate (2.20). Defining $W^h = r_h \tau^0 - w^h$, we obtain $W^h \in \varPsi_{0h}$.

In fact, $W^h \in N_h(\Omega)$ and, by virtue of the definition of $r_h$ (cf. Remark 2.4)

\[ T(W^h) = 0 \quad \text{on} \quad \Gamma_e, \]
\[ T_0(W^h) = 0 \quad \text{on} \quad \Gamma_0, \]
\[ T_t(W^h) = T_t(W^{h\|}) = 0 \quad \text{on} \quad \Gamma_K, \]
\[ T_n(W^h) = T_n(W^{h\|}) = T_n(r_h \tau^0) - \varphi^h = \psi^h \leq -g \quad \text{on} \quad \Gamma_K. \]

Hence (see also Remark 2.5) $W^h \in \varPsi_0$ follows.

Moreover, we show that

\[
2 \tau^0 - W^h \in \varPsi_0.
\]

In fact, both $\tau^0$ and $W^h$ satisfy homogeneous boundary conditions on $\Gamma_e$ for $T$ and on $\Gamma_0, \Gamma_K$ for $T$, respectively. Moreover,

\[
T_0(2 \tau^0 - W^h) = 2 T_0(\tau^0) - \psi^h \leq -g \quad \text{on} \quad \Gamma_K.
\]

Consequently, (2.27) follows.

Using Theorem 2.2, we write

\[
\| \tau^0 - W^h \|_{0,\Omega} \leq \| \tau^0 - r_h \tau^0 \|_{0,\Omega} + \| r_h \tau^0 - W^h \|_{0,\Omega} \leq
\]
\[
\leq C h^2 \| \tau^0 \|_{2,\Omega} + \| w^h \|_{0,\Omega},
\]

and for the last term Lemmas 2.6 and 2.5 imply

\[
\| w^h \|_{0,\Omega} \leq C h^{-1/2} \| \varphi^h \|_{0,\Gamma_K} \leq C_1 h^{3/2} \left\| \frac{d^2}{ds^2} T_n(\tau^0) \right\|_{0,\Gamma_K}.
\]

Finally, from Lemma 2.4 the error estimate follows. Q.E.D.

Remark 2.4. Let us discuss also the configuration of Example 3 in short, i.e., let $\Gamma_0 = 0$ and $\Gamma_K$ be a straight segment, parallel with the $x_1$-axis.

We construct a $\lambda$ satisfying (2.7), define $\varPsi_0$, the equivalent dual problem (2.9), $\varPsi_{0h}$ and the approximations (2.12). If $V_2 \leq 0$, $\varPsi_0$ contains the zero element and there exists a unique approximation $\tau^h$.

We can prove an analogue of Theorem 2.3, where the same regularity of $\tau^0$ is required, assumptions (A1), (A2) are preserved and (A3) is replaced by the following

$(A3')$: in $\Omega''$ the triangulations $\mathcal{T}_h$ contain a fixed rectangle $AUBC$, independent of $h$, with $AU = \Gamma_K$, which is divided into small rectangular elements. In $\Omega'$ the triangulations $\mathcal{T}_h$ satisfy the same conditions as in (A3).

The proof is based on a modified Lemma 2.5, where a moment equilibrium condition

\[
\int_{\Gamma_K} \psi^h s \, ds = \int_{\Gamma_K} T_n(r_h \tau^0) \, s \, ds
\]
is added, and on an analogue of Lemma 2.6. To prove the latter lemma, we employ
the idea of stress fields in a “beam” $AUBC$. Thus we obtain upper bounds $C \max_{r_K} |\varphi|$ for the linear stress vectors components on every side, as previously.

3. ALGORITHM FOR APPROXIMATIONS OF THE DUAL PROBLEM

In the theoretical analysis we used the stress vector components to determine the
stress fields $\tau \in N_\delta(\Omega) − \text{ cf. Theorem 2.1.}$ For practice, however, the stress tensor
parameters $\beta_1^i, \ldots, \beta_7^i$ ($i = 1, 2, 3$) (cf. Section 2.1) are more suitable. First we present a survey of some results of Watwood and Hartz [3], which can be employed immediately to construct an algorithm for the solution of the problem (2.12).

On every subtriangle $K_i$ the stress field is given as follows

$$\tau = \begin{bmatrix} \tau_{11} \\ \tau_{21} \\ \tau_{12} \end{bmatrix} = \frac{E}{\sqrt{(AE_0)}} \begin{bmatrix} \sqrt{A} & 0 & 0 & x_1 & 0 & x_2 \\ 0 & \sqrt{A} & x_1 & 0 & x_2 & 0 \\ 0 & 0 & \sqrt{A} & 0 & -x_2 & -x_1 \end{bmatrix} S = MS,$$

where $S \in \mathbb{R}^7$ is a vector of coefficients, $E$ Young’s modulus, $E_0$ a dimensionless quantity, being equal to the reference modulus, $A$ the area of $K_i$.

Let the origin of coordinates $(x_1, x_2)$ be at the center of gravity of $K_i$, the material be homogeneous and isotropic in $K_i$ with a Poisson’s constant $\sigma$. Then we have

$$\int_{K_i} a_{mjk} \tau_{mj} \tau_{kl} dx = S^T f S,$$

where $(t$ is the thickness of the element $K_i$):

$$f = \frac{tE}{E_0} \begin{bmatrix} \alpha A, \\ \beta A, \alpha A, \\ 0, 0, \gamma A, \alpha \delta_1, \\ 0, 0, 0, \alpha \delta_1 + \gamma \delta_2, \\ 0, 0, 0, (\beta + \gamma) \delta_{12}, \alpha \delta_2 + \gamma \delta_1, \\ 0, 0, 0, \beta \delta_{12}, \alpha \delta_{12}, \beta \delta_2, \alpha \delta_2 \end{bmatrix}$$

$$\delta_j = \frac{1}{A} \int_{K_i} (x_j)^2 dx_1 dx_2, \quad j = 1, 2, \quad \delta_{12} = \frac{1}{A} \int_{K_i} x_1 x_2 dx_1 dx_2;$$

$\alpha, \beta, \gamma$ are constants, specified for plane stress as

$$\alpha = 1, \quad \beta = -\sigma, \quad \gamma = 2(1 + \sigma)$$
and for plane strain as
\[ \alpha = 1 - \sigma^2, \quad \beta = -\sigma(1 + \sigma), \quad \gamma = 2(1 + \sigma). \]

Likewise we could derive
\[ \int_{K_i} a_{ijkl} t_{mj} t_{nk} dx = \left( \int_{K_i} \lambda B^{-1} M dx \right) S, \]
where \( \lambda = (\lambda_{11}, \lambda_{22}, \lambda_{12})^T \), \( M \) is the matrix from (3.1) and \( B^{-1} \) is a \( (3 \times 3) \) matrix of the corresponding inverse Hooke’s law.

Each of the stress vector components on a side \( a_i a_{i+1} \) can be expressed in terms of external parameters \( S^* \in \mathbb{R}^4 \) and a parameter \( p \in (\mathbb{R}, 1) \), as follows:
\[ T_1(p) = S_1^* + S_2^* p, \]
\[ T_2(p) = S_3^* + S_4^* p. \]
For example, consider the side \( a_2 a_3 \). Then \( p = -1 \) at \( a_2 \), \( p = 1 \) at \( a_3 \),
\[ S^* = \frac{1}{2l_a \sqrt{A}} C S, \]
where \( l_a \) is the length of \( a_2 a_3 \) and \( C \) the following \( (4 \times 7) \) matrix:
\[
C = \begin{bmatrix}
-2 \sqrt{(A)} (Y_2 - Y_3), & 0, & 2 \sqrt{(A)} (X_2 - X_3), & 0,
0, & 0, & 0, & 0,
0, & 2 \sqrt{(A)} (X_2 - X_3), & -2 \sqrt{(A)} (Y_2 - Y_3), & X_2^2 - X_3^2,
0, & 0, & 0, & -X_2^2 + X_3^2,
-2(X_2 Y_2 - X_3 Y_3), & -(X_2^2 - X_3^2), & -(Y_2^2 - Y_3^2), & 0,
-2(X_2 - X_3) (Y_2 - Y_3), & (X_2 - X_3)^2, & (Y_2 - Y_3)^2, & 0,
Y_2^2 - Y_3^2, & 2(X_2 Y_2 - X_3 Y_3), & 0, & 0,
-(Y_2 - Y_3)^2, & -2(X_2 - X_3) (Y_2 - Y_3), & 0, & 0
\end{bmatrix} \]
\[
\text{(a) (b) (c)}
\]

By a cyclic permutation of indices, the matrices \( C \) and \( C \) can be obtained. Denote the external parameters on the side \( b \) \( S_5^*, S_6^*, S_7^*, S_8^* \) and on \( c \) \( S_9^*, S_{10}^*, S_{11}^*, S_{12}^* \). For the total vector \( S^* \in \mathbb{R}^{12} \) it holds
\[ S^* = CS, \]
where the \( (12 \times 7) \) matrix \( C \) is composed of \( C, C, C \):
\[
C = \frac{1}{2 \sqrt{A}} \begin{bmatrix}
l_a^{-1} & (a) & C
l_b^{-1} & (b) & C
l_c^{-1} & (c) & C
\end{bmatrix}
\]
340
The conditions of continuity for the stress vector across any common side of adjoint triangles take the form

\[(3.5) \quad S^*_i + S^*_j = 0,\]

(where the indices \(i, j\) correspond with the same basis functions but with different triangles).

It is readily seen from the definition of \(\mathcal{U}_{oh} = \mathcal{U}_0 \cap N_h(\Omega)\), that \(\tau \in \mathcal{U}_{oh}\) if and only if:

- all constraints of the type (3.5) hold,
- \(S^*_j = 0\) on any side \(a_i a_{i+1} \subset \Gamma\),
- \(S^*_j t_1 + S^*_j t_2 = 0\) on \(\bar{\Gamma}_0 \cup \bar{\Gamma}_k\),

(3.6)

where \(t_k\) denote the tangential vector components and (3.7) hold independently for \(\tau^M \in N_h(\Omega^M), \ M = 1, 2\).

\[(3.7) \quad S^*_i + S^*_i + 2t^2 = 0 \text{ on } \bar{F}^K,\]

\[(3.8) \quad [S^*_i n_1 + S^*_j n_2 + (S^*_i n_1 + S^*_j n_2)]_{x'} \leq -g \text{ on } \bar{\Gamma}_K,\]

and conditions (3.5) for any common side of two triangles, which belongs to \(\bar{\Gamma}_k\).

The following compensation of parameters is recommended. In each triangular block-element we exclude the internal degrees of freedom. Let the conditions of continuity at the segment \(0a_i\) (see Fig. 1) be written as

\[(3.9) \quad A_u S = 0,\]

where \(A_u\) is a \((12 \times 21)\) matrix and \(S\) a \((21 \times 1)\) matrix. There exists a regular \((21 \times 21)\) matrix \(Q\) such that

\[(3.10) \quad A_u Q = [I \mid 0],\]

where \(I\) is the unit matrix. The matrix \(Q\) is not determined uniquely. It suffices even to replace \(I\) in (3.10) by any regular \((12 \times 12)\) matrix. Moreover, only the last nine columns of \(Q\), i.e. a matrix \(Q_1\), is needed.

Let us transform \(S\) as follows

\[(3.11) \quad S = QS = [Q_0 \mid Q_1] \begin{bmatrix} \hat{S}_u \\ \hat{S}_j \end{bmatrix},\]

where \(Q\) is divided between 12th and 13th column and \(\hat{S}\) accordingly. Substituting into (3.9), we obtain

\[A_u QS = [I \mid 0] \hat{S} = 0 \Rightarrow \hat{S}_u = 0\]

and the transformation (3.11) is reduced to

\[(3.12) \quad S = Q_1 \hat{S}_j,\]

341
where \( Q \) is a \((21 \times 9)\) matrix and \( S_t \) a \((9 \times 1)\) matrix. The parameters \( S_t \) are independent degrees of freedom of the block-element.

The functional \( J(\tau) \) of the equivalent dual problem can be evaluated in terms of \( S_t \):
\[
J(\tau) = \frac{1}{2} \sum_{k \in \mathcal{F}} \sum_{l=1}^{3} \int_{K_i} a_{mjk_l} \tau_{m_l} \tau_{kl} + 2 \Gamma_{kl} \) \( d\mathbf{x} = 
\]
\[
= \sum_{k \in \mathcal{F}} \sum_{l=1}^{3} (S_1^T J + B_0^T S) = \sum_{k \in \mathcal{F}} (S_1^T J + b_0^T S) = 
\]
\[
= \sum_{k \in \mathcal{F}} \left( \frac{1}{2} S_1^T Q_1^T F Q_1 \hat{S}_t + b_0^T Q_1 \hat{S}_t \right) = \frac{1}{2} S_1^T A \hat{S}_t + b_0^T \hat{S}_t = J(\hat{S}_t),
\]
(where the vectors \( S, \hat{S}_t \) correspond with a subtriangle, block-element and the whole triangulation, respectively). The \((N \times N)\) matrix \( A \) is positive definite.

Inserting (3.4) and (3.12) into the conditions of the type (3.5) — (3.8), we obtain the constraints
\[
(3.13) \quad DS_t = 0, \\
(3.14) \quad ES_t \leq -g,
\]
where \( D \) and \( E \) are \((p_1 \times N)\) and \((p_2 \times N)\) matrices, respectively, \( g \) a vector with identical components, equal to \( g \).

Let us define the set
\[
\mathcal{B} = \{ \hat{S}_t \in \mathbb{R}^N \mid (3.13) \text{ and } (3.14) \text{ are satisfied} \}.
\]
Thus we arrived at the problem to find \( \sigma \in \mathcal{B} \) such that
\[
J(\sigma) \leq J(\hat{S}_t), \quad \forall \hat{S}_t \in \mathcal{B}.
\]

One can apply e.g. the algorithm of Uzawa for solving (3.15) (cf. [2] — chpt. 5). Denote \( p = p_1 + p_2 \) and
\[
B = \begin{bmatrix} D \\ E \end{bmatrix}, \quad G = \begin{bmatrix} 0 \\ g \end{bmatrix}
\]
the \((p \times N)\) and \((p \times 1)\) matrix, respectively. Introduce the set of admissible Lagrange multipliers
\[
\mathcal{A} = \{ z \in \mathbb{R}^p \mid z_j \geq 0 \text{ for } j = p_1 + 1, \ldots, p \}.
\]
Choosing a \( z^0 \in \mathcal{A} \), we calculate \( s^0 \in \mathbb{R}^N \) from the system
\[
A \delta^0 = -b - B^T z^0.
\]
Having \( z^n, s^n \), the values of \( z^{n+1}, s^{n+1} \) are determined as follows
\[
z^{n+1} = P_A[z^n + \phi(B s^n + G)], \\
A s^{n+1} = -b - B^T z^{n+1},
\]
where
where $P_A$ denotes the projection onto the set $A$, i.e.,

$$y = P_A v \iff \begin{cases} y_j = v_j, & j = 1, \ldots, p_1 \\ y_j = \max \{0, v_j\}, & j = p_1 + 1, \ldots, p, \end{cases}$$

and $\varrho$ is a sufficiently small parameter.

It can be proven that $s^n \to \sigma$ in $\mathbb{R}^N$ for $n \to \infty$, where $\sigma$ is the (unique — see Lemma 2.3) solution of (3.15), provided that ran $g = p_1 + p_2$.

Finally, let us discuss again a possible construction of the auxiliary stress field $\lambda$ (cf. Section 2). Again, we consider the configuration of Example 1 and choose the boundary condition (2.2) on $\Gamma_K$. According to the interpretation of the set $K_{F,p}$ and (2.7) (see also Lemma 1.6 and Lemma 2.2), we may proceed as follows.

Choose $\lambda^{(1)} \in S$, satisfying the equations (1.18) in $\Omega = \Omega' \cup \Omega''$ (by simple integration with respect to $x_1$ or $x_2$).

Assume that $F$ is a constant vector field (zero or gravitational forces in most cases) and $P$ is a piecewise linear vector field. Then $\lambda_{ij}^{(1)}$ are linear polynomials over $\Omega$ and $T(\lambda^{(1)})$ are linear on every side of the polygonal boundaries $\partial \Omega' \cup \partial \Omega''$.

Setting $\lambda = \lambda^{(1)} + \lambda^{(2)}$ we may look for $\lambda^{(2)}$ in the space $N_h(\Omega)$, satisfying moreover the following boundary conditions

\begin{align}
(3.16) & & T(\lambda^{(2)}) &= P - T(\lambda^{(1)}) & & \text{on } \Gamma_1, \\
(3.17) & & T_i(\lambda^{(2)}) &= -T_i(\lambda^{(1)}) & & \text{on } \Gamma_0, \\
(3.18) & & T_i(\lambda^{(2)\|}) &= T_i(\lambda^{(1)\|}) = -T_i(\lambda^{(1)}) & & \text{on } \Gamma_K, \\
(3.19) & & T_i(\lambda^{(2)\|}) &= T_i(\lambda^{(1)}\|) = g - T_i(\lambda^{(1)}) & & \text{on } \Gamma_K.
\end{align}

Since the right-hand sides in (3.16)—(3.19) are linear or piecewise linear functions, the stress field $\lambda^{(2)}$ exists. It can be constructed using the procedure described above. We employ the parameters $\hat{S}_i$, and the formulas (3.1), (3.12), (3.4), write the continuity conditions of the type (3.5) and express the boundary conditions (3.16)—(3.19) in terms of $\hat{S}_i$ via (3.4) and (3.12). The undetermined values of $T_i(\lambda^{(2)})$ on $\Gamma_0$ and $T_i(\lambda^{(2)})$ on $\Gamma_i$, $i = 1, 2$, can be chosen in such a way that the resulting system of linear equations is solvable. The choice corresponds with the global equilibrium of the body $\Omega'$ and $\Omega''$, respectively.

Remark 3.1. The dual analysis enables us to find a posteriori error estimates and two-sided bounds of the exact energy. The derivation may follow e.g. the approach of [8] — Section 5.
