HOMOLOGICAL FIXED POINT THEOREMS, II.

Omar HÁJEK, Praha

This paper consists of some notes and generalisations of results of the preceding paper [4].

The first of these concerns lemma 2 of [4], stating that the invariant j of endomorphisms f of a group G is independent of the behaviour of f on the periodic part of G . Here we present a considerably stronger result in theorem 1.

The second extends a result of [4] (for a continuous $f : S^{2n} \rightarrow S^{2n}$, f^2 has a fixed point) to a more general class of spaces, admitting formation of cartesian products; lemma 1 and theorem 2.

The rôle which even-dimensionality plays in this result suggests the possibility of a connection with other familiar theorems having similar restrictions: Brouwer's theorem on antipodals [1, ch. XVI, § 5], or the "hedgehog theorem" of Poincaré (loc.cit., there is no nonzero tangent vector field on S^{2n}). A closer examination reveals that the resemblance is only superficial: the latter theorems admit a natural generalisation to e.g. odd-dimensional spheres, as will be shown in theorem 3; our result does not.

As in [4], we consider the category \mathcal{G}_J consisting of abelian groups with an integrity domain J as left operators, and of their operator homomorphisms. The reader is first re-

ferred to [2], exercises D in chap.IV. There it is shown how one may assign to each group G in \mathcal{G}_J a vector space G^\wedge over \hat{J} , the quotient field of J ; and to each $f : G \rightarrow G'$ in \mathcal{G}_J a \hat{J} -homomorphism $f^\wedge : G^\wedge \rightarrow G'^\wedge$. The resulting object turns out to be an additive exact covariant functor \wedge from \mathcal{G}_J to $\mathcal{G}_{\hat{J}}$. (The definition loc.cit. of the transitive relation \sim should, however, be corrected to: $[e_1, x_1] \sim [e_2, x_2]$ iff $\theta e_2 x_1 = \theta e_1 x_2$ for some $\theta \neq 0$ in J .) The circumflex \wedge will henceforth be used in this sense, and not in that of [4].

Exactness of \wedge then implies that, on the category $\mathcal{D}\mathcal{G}_J$ of differential groups over J , the homology functor and \wedge commute:

$$H(G^\wedge) = (H(G))^\wedge, \quad (f^\wedge)_* = (f_*)^\wedge.$$

It is noted (loc.cit.) that \wedge preserves ranks. Since $j(\text{id}_G) = (\text{rank } G)/(1 - \lambda)$ [4, section 1], this is the $f = \text{identity}$ special case of the following

Theorem 1. If $f : G \rightarrow G$ in \mathcal{G}_J , then $j(f) = j(f^\wedge)$.

By [4, definition 3], g_{li} depends on j ; thus theorem 1 implies $g_{li}(f) = g_{li}(f^\wedge)$ for $f : G \rightarrow G$ in the category of group sequences. In [4, theorem 3] it was shown that $g_{li}(f) = g_{li}(f_*)$ for $f : G \rightarrow G$ in the category of differential group sequences (i.e., complexes); our present result yields, then,

$$g_{li}(f) = g_{li}(f_*^\wedge)$$

Proof of theorem 1. There is a canonic mapping $c : G \rightarrow \hat{G}$ defined by $c x = (1, x)$; we have $c \in \text{Hom}_J(G, G^\wedge)$ and $c f = f^\wedge c$ for $f \in \text{Hom}_J(G, G)$. It is easily shown that, if B is a w -base in G [4, section 1], then $c(B)$ is linearly

independent and generates \hat{G} ; thus $c(B)$ is a base in \hat{G} .
 The relations

$$\theta_1 f x_i = \sum_j \alpha_{ij} x_j$$

used to define matrices D, A and then p, j [4, def.1 and 2] carry over to

$$\theta_1 f^c x_i = \sum_j \alpha_{ij} c x_j ;$$

thus they define the same matrices D, A and hence also p, j . This completes the proof.

Definition. A triangulable space will be called non-odd if all its odd-dimensional homology groups (over integer coefficients) are periodic.

This definition is a modification of an earlier inadequate version; the present formulation and also the proof of the lemma to follow were suggested to the author by Mr. A. Pultr, the referee.

Cells and even-dimensional spheres are non-odd, since their odd-dimensional homology groups are trivial. Even-dimensional projective spaces are non-odd, as may be shown directly. We note that the Euler characteristic of a non-odd space reduces to the sum of ranks of the even-dimensional homology groups; hence it is positive unless the spaces is empty.

Lemma 1. The cartesian product of two non-odd spaces is non-odd.

Proof. Let X, Y be non-odd; the Künneth formula (e.g. [3 , chap.I, th. 5.5.2]) is

$$H_n(X \times Y) = \sum_{p+q=n} H_p(X) \otimes H_q(Y) + \sum_{p+q=n-1} \text{Tor}(H_p(X), H_q(Y)) .$$

The second sum is always a periodic group; consider any summand in the first sum. For odd $n = p + q$, one of p, q is also odd, so that by assumption one factor is periodic; hence $H_p(X) \otimes H_q(Y)$ is periodic. This completes the proof.

It may be remarked that if the condition in the definition is strengthened to "all odd-dimensional homology groups are trivial", then the corresponding lemma no longer holds.

Theorem 2. Let $f : X \rightarrow X$ be a continuous mapping of a non-odd space $X \neq \emptyset$. Then one of

$$f, f^2, f^3, \dots, f^{\chi(X)}$$

has a fixed point.

As a trivial but weird example, for every map f of a finite set of n points into itself, at least one of f, \dots, f^n has a fixed point; this is easily checked directly, and in general, f^n cannot be replaced by a preceding iterate.

Corollary. $f^{\chi(X)}$ has a fixed point.

This includes our corollary to theorem 5 in [4], and also the Brouwer fixed - point theorem; $\chi(S^{2n}) = 2$, $\chi(E^n) = 1$ respectively. As concerns the conjecture in [4, section 3], we now have the following result. A space X consisting of the product of n cells and m even-dimensional spheres has as Euler characteristic $\chi(X)$ the product of characteristics of its factors, namely 2^m . Thus one of

$$f, f^2, f^3, \dots, f^{2^m}$$

does have a fixed point, but here one may not omit the f^1 with $1 \neq 2^j$ (e.g. for $X = S^0 \times S^0$).

Proof of the theorem 2. Let f_* be the homomorphism of the homology sequence of X , induced by f . From theorem 1,

$$g_{li}(f) = g_{li}(f_*^{\wedge}) .$$

From [4], section 3, lemma 4 and definition 3, we then have for the Lefschetz number J

$$(2) \quad J(f^R) = J(f_*^{\wedge R}) = \sum_q \text{tr} (f_{*2q}^{\wedge R})$$

since by our assumption on X , $H_q(X)^{\wedge} = 0$ for odd dimensions

q . Finally, from the proof of theorem 2 in [4],

$$(3) \quad \text{tr}(f_{*2q}^{\wedge r}) = \sum_{j=1}^{r_q} \lambda_{j,q}^r$$

where $r_q = \text{rank } H_r(X) = \text{rank } H_q(X)$, and $\lambda_{j,q}$ are certain complex numbers (characteristic roots of certain matrices $D_{2q}^{-1} A_{2q}$). It is known that $\text{tr}(f_{*0}^{\wedge r}) = 1$ if X is connected (e.g. [1], chap. XVII, § 1); in our case we have at least that $\text{tr}(f_{*0}^{\wedge r}) = m$, a positive integer since X is nonempty.

Substitute (3) into (2), omit all $\lambda = 0$, assemble all $\lambda = 1$, and finally all equal λ 's. Thus we may write

$$J(f^r) = m_0 + \sum_{j=1}^{\chi(X)-1} m_j \lambda_j^r$$

with $m_j \geq 0$ integers, $m_0 > 0$, λ_j 's distinct with $0 \neq \lambda_j \neq 1$. (By non-oddness, $\chi(X) = \sum \text{rank } H_{2q} = \sum r_{2q}$; thus there are at most $\chi(X)$ distinct λ_j , of which at least one is included in the m_0 term.

With notation thus established, assume that the assertion of the theorem does not hold. Thus the iterate f^r with $1 \leq r \leq \chi(X)$ has no fixed points, and from the Hopf-Lefschetz theorem we obtain $\chi(T)$ equations $J(f^r) = 0$. Subtracting the r -th from the following there results

$$\sum_{j=1}^{\chi(X)-1} m_j \lambda_j^{r-1} (\lambda_j - 1) = 0 \quad (1 \leq r \leq \chi(X) - 1).$$

Consider these as a system of equations in unknowns m_j . Obviously the determinant of the system is

$$\Delta = \prod_j \lambda_j \times \prod_j (\lambda_j - 1) \times V(\dots \lambda_j \dots)$$

with V the Vandermonde determinant. Since by construction the λ_j are all distinct and $0 \neq \lambda_j \neq 1$, we conclude $m_j = 0$ for all j . Thus our relations $J(f^r) = 0$ reduce to $m_0 = 0$; this contradiction with $m_0 > 0$ proves our theorem.

To unburden the formulation of the theorem to follow, we first introduce, provisionally, two new terms.

A topological space T may be called sphere-like if it is triangulable connected, with positive dimension n , and

$$H_q(T) = 0 \text{ for } 0 < q < n, \text{ rank } H_n(T) = 1.$$

Obviously, spheres are sphere-like; however S^0 and e.g. $S^n \times S^m$ or E^n are not ($n > 0$).

A homeomorphism $h : T \rightarrow T$ of a sphere-like space will be called positive or negative in accordance with the sign of its degree. This latter term may be introduced for continuous maps $f : T \rightarrow T$ (sphere-like) as follows. Take any element $x \in H_n(T)$ of infinite order; since $H_n(T)$ has rank 1, there exists integers $\theta \neq 0$ and α such that

$$\theta f_{*n} x = \alpha x;$$

then set

$$\text{degree}(f) = \frac{\alpha}{\theta}.$$

This is easily shown to be independent of the choice of x , θ ,

α . (In the notation of [4], $\text{degree}(f) = \text{tr}(f_{*n}) = \frac{d}{d\lambda} j_n(f; \lambda)|_{\lambda=0}$.) If $T = S^n$, $H_n(S^n)$ is infinite cyclic

and $\text{degree}(f)$ is an integer, and coincides with the customary concept. If f is a homeomorphism, $\text{degree}(f) = \pm 1$; for T a simply connected region in S^2 this coincides with the sign of f as defined in [4, p. 433]. The identity map is a positive homeomorphism; if $T = S^n$, then change of sign of k of the $n+1$ coordinates is positive or negative according as k is even or odd.

Theorem 3. Let $f : T \rightarrow T$ be a continuous map of a sphere-like space T . Then

$$f x = h x$$

is solvable in T , either for all positive or for all negative homeomorphisms $h : T \rightarrow T$. If f itself is a homeomorphism, then precisely one of these alternatives holds.

Proof. With the Hopf-Lefschetz theorem, the proof is almost trivial: it sufficed to consider existence of fixed points of $h^{-1}f$, and

$$\begin{aligned} J(h^{-1}f) &= 1 + (-1)^n \text{degree}(h^{-1}f) = \\ &= 1 + (-1)^n \text{degree}(h) \text{degree}(f) \neq 0 \end{aligned}$$

for at least one of $\text{degree}(h) = \pm 1$. If also $\text{degree}(f) = \pm 1$, then there is precisely one possibility.

As an example, take $T = S^{2n}$. Then either $fx = x$ is solvable ($h = \text{identity}$, $\text{degree}(h) = 1$) or $fx = -x$ is solvable ($hx = -x$, $\text{degree}(h) = (-1)^{2n+1} = -1$). This is Brouwer's theorem on antipodals.

Theorem 3 suggests that it may be interesting to obtain further results on solvability of

$$f x = g x$$

for given continuous $f, g : X \rightarrow X'$.

A problem was formulated in [4], to prove

$$(4) \quad J(f) = \chi(A)$$

for all maps $f : X \rightarrow X$ of a triangulable space X and with A the set of fixed points of f . A class of maps was exhibited for which the stronger relation

$$g_{li}(f) = \frac{\chi(A)}{1 - \lambda}$$

holds [3, theorem 6]. The desirability of formula (4) follows from the information concerning A which could be obtained from rather superficial information about f ; e.g., the Hopf-Lefschetz fixed point theorem would follow.

However, the conjecture is not valid, and the heuristics which led to it were not sufficiently careful: there is a

simple counter-example. Take $X = S^1$, treated as the unit circle in the complex plane. Let f be defined by $f x = x^d$, d integer. Then f has degree d [2, ch.XI, theorem 4.5], and thus

$$J(f) = 1 - d .$$

For $d \neq 1$, f has precisely $|d - 1|$ fixed points, and in any case

$$\chi(A) = |d - 1|$$

for the set A of fixed points of f . Thus $J(f) \neq \chi(A)$ for $d > 1$.
