# TORSION QUASIMODULES <br> T. KEPKA and P. NEMEC 

Abstract: Using the preradical approach, torsion and cocyclic quasimodules are investigated. It is aiso shown how varieties of quasimodules are constructed from varieties of modules and 3-elementary commutative Moufang loops.

Key mords: Commutative Moufang loop, quasimodule, preredical, variety of quasimodules.

Classifioation: 2ONO5

## 1. Introduction

A loop $Q(+)$ satisfying the identity $(x+x)+(y+z)=$ $=(x+y)+(x+z)$ is commutative and it is called a commutative Moufang loop. We denote by $\underline{C}(Q(+))$ the centre of $Q(+)$, i.e. a e $\underline{C}(Q(+))$ iff $(a+x)+y=a+(x+y)$ for all $x, y \in Q$. Then $\underline{\mathbf{C}}(Q(+))$ is a normal subloop of $Q(+)$, $3 x \in \underline{\mathbf{O}}(Q(+))$ for every $x \in Q$ and we have the upper central series $0=\underline{G}_{0}(Q(+)) \subseteq$

 The loop $Q(+)$ is said $t c$ be nilpotent of class at most $n$ if $C_{n}(Q(+))=Q$. Further, for all $x, y, z \in Q$, the associator $[x, y, z]$ is defined by $[x, y, z]=((x+y)+z)-(x+(y+z))$ and we
denote by $\triangle(Q(+))$ the subloop generated by all associatore. Then $\triangleq(Q(+))$ is normal aubloop of $Q(+)$ and $3 x=0$ for every $x \in(Q(+))$ - Moreover, we have the lower central series $Q=\AA_{0}(Q(+)) \supseteq \AA_{1}(Q(+)) \supseteq \AA_{2}(Q(+)) \supseteq \ldots \geq \AA_{n}(Q(+)) \supseteq \ldots$ of $Q(+)$, where $A_{\mathrm{n}+1}(Q(+))$ is the aubloop generated by all associator: $[x, y, s], x \in \mathcal{A}_{1}(Q(+)), y, z \in Q$, for every $n=0,1,2, \ldots$ The loop $Q(+)$ is nilpotent of class at most $n$ iff $A(Q(+)) \subseteq$
 As for details and further information concerning commatave Moufeng loops, the reader is referred to [5].

Let $Q(+)$ be a commutative Moufang loop. A mapping $f$ of $Q$ into $Q$ is said to be n-central, $n$ being an integer, if $n x+f(\bar{X}) \in \underline{C}(Q(+))$ for every $x \in Q$. Clearly, $f$ is n-central iff it is m-central, where $m \in 0,1,2\}$ and $n=3 k+m$. The sero endomorphise $x \rightarrow 0$ is 0-central, the automorphisin $x \rightarrow-x$ is 1-central and the identical automorphiam $x \rightarrow x$ is 2-central. As proved in $[9]$, the set of all ( $0,1,2-$ ) central endomorphisms of $Q(+)$ is an associative ring with unit.

Throughout the paper, let $R$ be an associative ring with unit, $\Phi$ a ring homomorphism of $\underline{R}$ onto the three-element field $\underline{Z}_{3}=\{0,1,2\}$ and $\underline{I}=$ Ker $\Phi$. By a ( $\Phi$-apecial unitary left $\mathrm{R}_{-}$) quacimodule $Q$ we mean a commutative Moufang loop $Q(+)$ equipped with scalar mitiplication by elements of F auch that the usual module identities are satisfied, i.e. $r(x+y)=r x+r y$, $(r+s) x=r x+s, r(s x)=(r s) x, 1 x=x$ for all $r, s \in R$, $x, y \bullet Q$ and, moreover, $t x \in \underline{C}(Q(+))$ for all $x \in Q$ and $t \in I$. The last condition says that the endomorphism $x \rightarrow r x$ of $Q(+)$
is (- $\overline{( }(r)$-central for all $r$ e . Some information concerning quasimodules and constructions of non-associative quasimodules can be found in $[9],[10]$ and $[11]$.

Let $Q$ be a quasimodule. A subquasimodule $P$ of $Q$ is normal in $Q$ (i.e. $P$ is a block of a congruence of $Q$ ) iff $P(+)$ is a normal subloop of $Q(+)$. Now it is easy to see that all the members of the upper central series as well as of the lower central series of $Q(+)$ are normal subquasimodules of $Q$. Hence $Q$ is said to be nilpotent of class at most $n$ iff the loop $Q(+)$ is so. Purther, we shall say that $Q$ is a primitive quasimodule if $r x=0$ for all $r e I$ and $x \in Q$. 1.1 Exaple. Every commutative Moufang loop (abelian groups included) is a $\underline{z}$-quasimodule, $\underline{Z}$ being the ring of integers and $\Phi$ the natural homomorphism of $\underline{Z}$ onto $\underline{Z}_{3}$. 1.2 Example. Let $Q(+)$ be a 3-ezementary commutative Moufang loop. Put $r x=\Phi(r) x$ for all $r \in R$ and $x \in Q$. Then $Q=$ $=Q(+, r x)$ is a primitive quasimodule and we see that the classes of prinitive quasinodules, $\underline{Z}_{3}$-quasimodules and 3-elementary commutative Moufang loops are equivalent.
1.3 Exaple. Let $Q(+)$ be a non-associative comutative Moufang 100p. Denote by $R$ the ring of central endomorphisme of $Q(+)$. For every $f \in \mathbf{R}$ there is anique $n(f) \in\{0,1,2\}$ such that $f$ is $n(f)$-contral and the mapping $f \rightarrow-n(f)$ is a ring homomorphis of $R$ onto $\underline{Z}_{3}$. How, $Q$ has on R-quasimodule etructure. 1.4 Exopple. A quasigroup $\%$ is add to be trimedial if every subquasigroup of $G$ generated by at most 3 elements is medial,

```
i.e. satisfies the identity xy.uv = ma.yV . Trimedial and me-
dial quasigroups appear in many geometrical situations (see e.g.
[1], [4],[15],[16]) and important classes of trimedial
quasigroups are idempotent trimedial quasigroups (called also
distributive quasigroups and determined by the identities x.ys=
Iy.x% , ym.x = yx.Ex ), symmetric trimedial quasigroup: (better
known as CH-quasigroups or Manin quasigroups and determined by
the identities }xy=yx,x.xy=y and xx.yz = xy.xs ) and idem-
potent symmetric trimedial quasigroups (distributive Steiner
quasigroups know in an equivalent form as Hall triple ayeteme).
Now, let }R=\underline{Z}[x,y,\mp@subsup{x}{}{-1},\mp@subsup{y}{}{-1}]\mathrm{ . As proved in [12] , the classes
of pointed trimedial quasigroups and contrally pointed quasimo-
dules are equivalent.
1.5 Proposition. Let }n\mathrm{ be a positive integer.
(i) Erery quasimodule which cam be generated by at most n ele-
ments is nilpotent of class at most m mame(1,n-1).
(ii) The free primitive quasimodule of rank n (and honce the
free quasimodule of rank n ) is nilpotent of clase precisely m.
Proo1. (1) See [9, Proposition 4.3]; the assertion is accomee-
quence of the same result for commutative Moufang loops which is
known as the Bruck-Slaby's theorem ([5, Theorem VIII,10.1]).
(ii) See [2, Corollary IV.3.2].
1.6 Proposition. Let Q be a quasimodule. Then both A(Q) and
Q/\underline{C(Q) are primitive.}
Proof. Let re I .We have rxe G(Q) for all x e Q and it is
clear that Q/\underline{C}(Q) is primitive. On the other hand, the mapping
```

$f: x \rightarrow r x$ is an endomorphism of $Q(+)$ and In $f \subseteq \underline{G}(Q(+))$. Consequently, Im $f$ is associative, hence $A(Q) \subseteq$ Ker $f$ and $r y=0$ for all $y \in \Lambda(Q)$.
1.7 Proposition. (1) Every simple quasimodule is a module.
(ii) Every maximal subquasimodule of a nilpotent quasimodule is normal.
(iii) If the ring $\underline{R}$ is left noetherian then every subquasimodule of a finitely generated quasimodule is finitely generated.

Proof. See [9, Lamma 4.8, Corollary 4.11, Proposition 4.6].
Let $Q$ be quasimodule. For all $a, b \in Q$, define a mapping $i_{a, b}$ by $i_{a, b}(x)=((x+a)+b)-(a+b)$. Then $i_{a, b}$ is an automorphise of the loop $Q(+)$ and $i_{a, b}(x)=x+[x, a, b]$.
1.8 Lemas. Let $P$ be a subquasimodule of a quasimodule $Q$. The following conditions are equivalent:
(i) $P$ is a normal subquasimodule of $Q$.
(ii) $i_{a, b}(P) \subseteq P$ for all $a, b \in Q$.
(iii) $[x, a, b] \in P$ for $a l l x \in P, a, b \in Q$.

Proof. Easy.
1.9 Lema. Let $Q$ be a quasimodule and $a, b \in Q$. Then $i_{a, b}$ is an automorphism of the quasimodule $Q$.

Proof. Let $r \in$ ㄹ be arbitrary and $s=-\Phi(r) .1$. We have $(r+g) \times \underline{C}(Q)$ for every $x \in Q$. Denote $c=(x+s) a, d=(r+B) b$. Then $1_{a, b}(x)+i_{a, b}(r x)=i_{a, b}((r+s) x)=(x+b) x$ and $(r+s) I_{a, b}(x)=i_{c, d}((r+s) x)=(r+s) x$. Consequently, $i_{a, b}(r x)=$ $=r 1_{a, b}(x)$.

## 2. Preradicals

By a preradical $p$ (for quasimodules) we mean any subfunctor of the identity functor, i.e. $p$ assigns to each quasimodule $Q$ a subquasimodule $p(Q)$ in such a way that $f(p(Q)) \subseteq$ $\subseteq p(P)$ whenever $f$ is a homomorphise of $Q$ into a quasimodule $P$. The basic properties of preradicals for quasimodules are the same as in the module case and the reader is referred to [3] and [9] for details. We shall also use the termanology introduced in [3]. Recall that a preradical $p$ is eaid to be hereditary if $p(P)=P \cap p(Q)$ whenever $P$ is a subquasimodule of a quasimodule $Q$. $\Lambda$ preradical $p$ is said to be cohereditary if $f(p(Q))=p(P)$ whenever $f$ is a surjective homomorphism of a quasimodule $Q$ onto quasimodule $P$. If $p$ is a preradical then by $1.9 p(Q)$ is a normal subquasimodule of $Q$ for every quasimodule $Q$. Further, $p$ is said to be a radical if $p(Q / p(Q))=0$ for every quasimodule $Q$.
2.1 Exaple. It is easy to see that for every integer $n \geqslant 0$, $A_{2}$ is cohereditary radical. On the other hand, $C$ is not a preradical, since the centre is in general preserved only by surfective homomorphisms.
2.2 Example. For every quasimodule $Q$, let $B(Q)$ denote the least normal subquasimodule of $Q$ such that the corresponding factor is primitive. Then $B$ is cohereditary radical. By 1.6, $\underline{B}(Q) \subseteq \underline{C}(Q) \quad$.
2.3 Lemea. Let $Q$ be quasimodule generated by a set $M$. Then
$B(Q)$ is just the subloop of $Q(+)$ generated by all rx, $r$, x $\quad 1$ 。

Proof. Denote by $P$ that subloop. Since $I$ is an ideal, it is easy to verify that $P$ is a subquasimodule and $r y$ e $P$ for all $r \in I, J \in Q$. Purther, $P$ is normal and hence $P=\underline{B}(Q)$ :
2.4 Example. For every quasimodule $Q$, let $\underline{D}(Q)$ denote the least normal subquasimodule such that the corresponding factor is a $\underline{Z}_{3}$-module, i.e. a vector space over $\underline{Z}_{3}$. Then $\underline{D}$ is a cohereditary radical and, moreover, $\underline{D}=\underline{A}+\underline{B}$, i.e. $\underline{D}(Q)=$ $=\{x+y ; x \in \underline{A}(Q), y \in \underline{B}(Q)\}$ for every quasimodule $Q$.
2.5 Example. For every quasimodule $Q$, let $\mathcal{J}(Q)$ denote the intersection of all maximal normal subquasimodules of $Q ; \mathcal{J}(Q)=$ $=Q$ if there are no such subquasimodules. Clearly, $\mathcal{J}(Q)$ is just the intersection of all Ker $P$, $P$ ranging over all homomorphisms of $Q$ into simple (quasi)modules. Thus $J$ is a radical and $A \leq \underline{J} \leq D$ (use 1.7).
2.6 Proposition. Let $Q$ be a quasimodule.
(i) J(Q) is the intersection of all normal maximal subquasimodules of $Q$.
(ii) If $Q$ is nilpotent then $J(Q)$ is the intersection of all maximal subquasimodules of $Q$.
(iii) Let $Q$ be finitely generated, $P \subseteq \underline{J}(Q)$ be a normal aubquasimodule of $Q$ and let $f$ denote the natural homomorphisa of $Q$ onto $Q / P$. If $M$ is a subset of $Q$ such that $f(M)$ generates $Q / P$ then $Q$ is generated by $M$.

Proof. (i) and (ii) follow from $1.7(i),(i i)$, respectively.
(iii) Assume, on the contrary, that $Q$ is not generated by $M$ and let $N$ be a inite set generating $Q$. Purther, let $K$ be a subset of $N$ maximal with respect to the property that $M \cup K$ do not generate $Q$ and take a $N \backslash K$. There is a subquasinodule $G$ of $Q$ maximal with respect to $M \cup K \subseteq G$ and $a \notin G$. It is easy to see that $G$ is a maximal subquasimodule of $Q$ and hence $P \subseteq G$, a contradiction.

Let $\mathcal{F}$ be a filter of left idealy of the ring $R$. Por every quasimodule $Q$, let $p(Q)$ denote the set of all $x \in Q$ suoh that $(0: x)=\{r e \underline{R} ; r x=0\} \in \mathcal{F}$. Then $p=p_{\mathcal{F}}$ is a hereditary preradical.

### 2.7 Proposition. There is a one-to-one correspondence between

 hereditary preradicals and filters of left ideals given by$$
\begin{aligned}
& \mathcal{F} \rightarrow p(Q)=\{x \in Q ;(0: x) \text { ef } \mathcal{F}\} \\
& p \rightarrow \mathcal{F}_{p}=\{I \subseteq \underline{R} ; p(\underline{R} / I)=R / I\} .
\end{aligned}
$$

This correspondence induces a one-to-one correspondence between hereditary radicals and radical filters.

Proof. See [9, Proposition 3.2, Lema 3.3, Lema 3.4].
Let $p$ be a preradical. Define a preradical $\hat{p}$ by $\hat{p}(Q)=$ $=\cap$ Ker $I, f: Q \rightarrow P, p(P)=0$. Clearly, $\hat{p}$ is a radical and it is just the least radical containing $p$.
2.8 Lemma. Let $p$ be a preradical. Then a quasimodule $Q$ is $\hat{p}$-torsion iff there are an ordinal number $\alpha$ and a chain $Q_{\beta}$, $0 \leqslant \beta \leqslant \alpha$, of normal subquasimodules of $Q$ such that $Q_{0}=0$, $Q_{\alpha}=Q$ and $Q_{\beta+1} / Q=p\left(Q / Q_{\beta}\right)$ for every $0 \leqslant \beta<\alpha, Q_{\beta}=$ $=\bigcup_{\gamma<\beta} Q_{\gamma}$ for $\beta$ limit.

Proof. Obvious.
2.9 Lemma. Let $p$ be a hereditary preradical. Then $\dot{p}$ is a hereditary radical.

Proof. See [9, Proposition 3.7].
Let $A$ be a simple module. Then $A$ is isomorphic to $R / I$ for a maximal left ideal $I$; we denote by $\mathcal{F}=\mathcal{F}_{I}\left(\mathbb{R}=\mathbb{R}_{I}\right)$ the filter (radical filter) generated by $I$ and we put $\underline{S}_{A}=p_{g}$. By 2.7 and 2.9, $\underline{S}_{A}=p_{Q}$.

The field $\underline{Z}_{3}$ considered as a module is simple and isomorphic to $\underline{R} / \underline{I}$. We shall also use the notation $\underline{L}=\underline{S}_{\underline{Z}_{3}}$ and $\underline{K}=\underline{L}$. Finally, denote by $\mathcal{F}$ (resp. $\mathbb{R}$ ) the filter (radical filter) generated by all maximal left ideals and put $\underline{S}=p_{\mathcal{F}}$, so that $\hat{S}=\mathbf{p}_{Q}$.

## 3. $\mathrm{S}-$ and $\mathbf{s}$-torsion quasimodules

3.1 Proposition. A quasimodule $Q$ is L-torsion iff it is primitive.

Proof. Obvious.
3.2 Proposition. Let $Q$ be a finitely generated primitive quasimodule. Then $Q$ is finite and $|Q|=3^{n}$ for some $n \geq 0$. Proof. The field ${\underset{Z}{Z}}^{Z}$ is clearly a noetherian ring and the result follows from $1.7(i i i)$ by induction on the nilpotence class of $Q$. 3.3 Proposition. For every quasimodule $Q, A(Q) \subseteq \underline{L}(Q) \subseteq \underline{X}(Q) \subseteq$ $\subseteq \underline{\underline{S}}(Q)$ and $\underline{A}(Q) \subseteq \underline{L}(Q) \subseteq \underline{S}(Q)$. Consequently, every K-torsionfree quasimodule (and also every St-torsionfree quasimodule) is a module.

Proof. This follows from 1.6.
3.4 Corollary. Let $A$ be a simple module not isomorphic to $\underline{Z}_{3}$. Then every $\underline{S}_{\boldsymbol{A}}$-torsion quasimodule is a module.

How, denote by $\varphi$ a representative set of simple modules such that $\underline{z}_{3} \in \mathscr{Y}$.
3.5 Proposition. Let $Q$ be an S-torsion quasimodule. Then $Q$ is a direct vu of subquatmodules $\underline{S}_{A}(Q)$, A © $\varphi$. If $A \neq \underline{Z}_{3}$ then $\underline{S}_{A}(Q)$ is a module isomorphic to a direct on of copies of $A$. If $A=\underline{z}_{\mathbf{z}}$ then $\underline{S}_{\mathbf{A}}(Q)$ is a primitive quasimodule. Proof. Pirst, let $B \in Y$ be arbitrary and let $P$ be the subquasimodule generated by $U \underline{S}_{A}(Q), A \in Y, A \neq B$. Let $\mathcal{F}$ be the filter generated by all maximal left ideals $I$ such that $B / I$ is not isomorphic to $B$ and let a $S_{-B}(Q) \cap P$. Then the cyclic module $\mathrm{Ra}_{\mathrm{a}}$ is both $\underline{S}_{B}$-torsion and $\mathrm{p}_{\mathrm{F}}$-torsion (both $\underline{S}_{B}$ and $p_{f}$ are hereditary and $P$ is $p_{F}$-torsion), so that $a=0$. Now, suppose that $B=\underline{Z}_{3}$. Then $(P+\underline{C}(Q)) / \underline{C}(Q)$ is both L-torsion and $p_{g}$-torsion, hence it is a zero module and $P \subseteq \underline{C}(Q)$. In particular, $P$ is a module and the sum $\underline{L}(Q)+P$ is direct. Finally, $\underline{A}(Q) \leq \underline{L}(Q)$ and $Q / \underline{A}(Q)=(\underline{I}(Q)+P) / \underline{A}(Q)$. From this, $Q=L(Q)+P$ and the rest is clear.
3.6 Theoren. Suppose that the ring R has primary decompositions. Let $Q$ be an St-torsion quasimodule. Then $Q$ is a direct sum of subquasimodules $\underline{\underline{S}}_{A}(Q), \perp \in Y$. If $A \neq \underline{Z}_{3}$ then $\underline{-}_{A}(Q)$ is a module.

Proof. We have $A(Q) \subseteq \underline{I}(Q)$ and $Q / A(Q)$ is generated by the inage of $U \underline{S}_{A}(Q), A$. Hence $Q$ is generated by this set and we can proceed in the same way as in the proof of 3.5.
3.7 Proposition. Let $Q$ be a finite $\underline{K}$-torsion module. Then $|Q|=$
$=3^{n}$ for some $n \geq 0$.

Proof. The assertion is an easy consequence of 3.2.
3.8 Lemma. Let $I$ be an ideal of $\underline{R}$ and let $Q$ be the radical filter generated by I . Then:
(i) A left ideal $K$ belongs to $Q$ iff for every sequence
$a_{1}, a_{2}, \ldots$ of elements of $I$ there is $n \geq 1$ with $a_{n} \ldots a_{1} e K$. (ii) If $I$ is finitely generated as a left ideal then a left ideal $K$ belongs to $Q$ iff $I^{n} \subseteq K$ for some $n \geq 1$. Proof. See e.g. [3, Corollary III.4.6, Proposition III.4.4]. 3.9 Corollary. Let $Q$ be a quasimodule. Then $x \in(Q)$ iff for every sequence $a_{1}, a_{2}, \ldots$ of elements of $I$ there is $n \geq 1$ with $a_{n} \ldots a_{1} x=0$. Moreover, if $I$ is finitely generated as a left ideal then $x \in \underline{X}(Q)$ iff $\underline{I}^{n} x=0$ for some $n \geq 1$.
3.10 Lemma. Let $I$ be a finitely generated maximal left ideal of the ring $\underline{R}$ such that $I$ is an ideal and $A=R / I$ is finite. Then every finitely generated $\underline{\underline{S}}_{\mathbf{A}}$-torsion module is finite. Proof. Clearly, $I^{n} / I^{n+1}$ is finitely generated and $B / I^{n}$ is finite for every $n \geq 1$. By $3.8(i i)$, every cyclic ${\underset{\sim}{n}}_{\mathbf{n}}$-torsion module is finite and the rest is clear.
3.11 Proposttion. Suppose that $I$ is finitely generated as a left ideal. Then every finitely generated $K$-torsion quasimodule $Q$ is Pinite.

Proof. We shall proceed by induction on the nilpotence class $n$ of $Q$. If $n \leq 1$ then $Q$ is a module and the result follows from 3.10. Now, let $n \geq 2$. We have $A_{n}(Q)=0, A_{n-1}(Q) \subseteq \underline{C}(Q)$ and $G=Q / A_{n-1}(Q)$ is finite by the induction hypothesis. There are two finite subsets $N$ and $M$ of $A_{n-2}(Q)$ and $Q$, respec-
tively, such that $\left(N+\Lambda_{n-1}(Q)\right) / \Lambda_{n-1}(Q)=A_{n_{n-2}}(Q) / \Lambda_{n-1}(Q)$ and $\left(M+A_{n-1}(Q)\right) / A_{n-1}(Q)=\theta$. Denote by $P$ the subquasimodule generated by all the associators $[x, y, z], x \in \mathbb{I}, y, z \in M$. Then $P$ is a finitely generated subquasimodule of $A_{n-1}(Q)$ and hence $P$ is a normal finitely generated submodule of $Q$. In particular, $P$ is finite. On the other hand, if $u \in \Lambda_{\perp-2}(Q)$ and $V, w \in Q$ are arbitrary, then $u=x+a, v=y+b, w=s+c$ for some $x \in J$, $y, z \in I$ and $a, b, c \in \underline{c}(Q)$. We have $[u, v, w]=[x, y, z] \in P$ and we see that $P=A_{n-1}(Q)$. Thus both $A_{n-1}(Q)$ and $G$ are finite, so that $Q$ is finite, too.
3.12 Proposition. Let $I$ be a finitely generated maximal left ideal of $R$ such that $I$ is an ideal and $A=R / I$ is inite. Then every finitely generated $\underline{S}_{\mathbf{A}}$-torsion quasinodule is finite. Proof. By 3.4, 3.10 and 3.11.
3.13 Theorem. Suppose that every maximal left ideal of $B$ is an ideal, finitely generated as a left ideal, maximal ideals commute and every simple module is finite. Let $Q$ be a finitely generated $\underline{\text { St-torsion quasimodule. Then } Q \text { is finite and there are }}$ $\Lambda_{1}, \ldots, A_{n} \in Y$ such that $Q$ is isomorphic to the product $\underline{\underline{s}}_{\mathbf{A}_{1}}(Q) \times \ldots \times \underline{\underline{s}}_{\mathbf{A}_{\mathbf{n}}}(Q)$. Proof. The ring $\underline{R}$ has primary decompositions and the result now follows from 3.6 and 3.12 .
3.14 Remark. The assumptions of the preceding theorem are satisfied e.g. if $R$ is a finitely generated commutative ring.
3.15 Proposition. Suppose that R is left noetherian. and every simple module is finite. Then every finitely generated S-torsion quasimodule is finite.

Proof. In the situation of Lema 2.8, $\infty$ is finite by $1.7(i 1 i)$
and we can proceed by induction, using 3.5 and 3.2.

## 4. Cocyclic quasimodules

A quasinodule $Q$ is said to be oocyclic if it contains a (non-zero) normal simple submodule $A$ such that $A$ is contained in every non-zero normal subquasimodule of $Q$. •
4.1 Lemma. Let $Q$ be a quasimodule and $A$ be a normal simple subquasimodule of $Q$. Then $A \subseteq \underline{C}(Q)$.

Proof. Let $a \in A$ and $x, y \in Q$ be arbitrary. Denote by $P$ the subquasinodule generated by $a, x, y$. Then $P$ is a nilpotent quasimodule and $A \leq \underline{C}(P)$ by [9, Lemma 4.7]. Consequently, $(a+x)+y=a+(x+y)$ and we have proved that $A \subseteq \underline{C}(Q)$.
4.2 Proposition. Let $Q$ be a cocyclic quasimodule and $A$ be the normal simple submodule of $Q$. Then:
(i) $A \subseteq \underline{C}(Q)$ and $\underline{\underline{s}}(Q)=\underline{S}_{A}(Q)$.
(ii) $Q$ is subdirectly irreducible.
(iii) Either $A \subseteq A(Q)$ and $A$ is isomorphic to $\underline{Z}_{3}$ or $Q$ is a module.
(iv) $\underline{C}(Q)$ is a cocyclic module.

Proof. Easy (use 4.1).
4.3 Corollary. A quasinodule $Q$ is cocyclic iff $\underline{C}(Q) \neq 0$ and Q is subdirectly irreducible. In particular, a nilpotent (resp. finitely generated) quasimodule is cocyolic iff it is subdirectly irreducible.
4.4 Proposition. Suppose that R is comeutative and noetherian. Let $Q$ be a cocyclic quasimodule and $A$ the normal simple aubmodule of $Q$. Then:
(i) $Q$ in $\underline{s}_{A}$-toraion.
(ii) If $Q$ is finitely generated and $A$ is finite then $Q$ is finite.
(iii) If $Q$ is non-associative then $A$ is isomorphic to $\underline{Z}_{3}$ and $Q$ is t-torsion.
(iv) If $Q$ is finitely generated and non-associative then $Q$ is finite.

Proof. Pirst, let $Q$ be a module. By [3, Proposition VI.3.4], ㅛ is a stable ring and so the injective hull $E$ of $Q$ is $\underline{\underline{s}}_{A}$-torsion. How, suppose that $A$ is isomorphic to $\underline{Z}_{3}$. We have $\Delta \subseteq \underline{\mathbf{C}}(Q)$ and $\underline{Q}(Q)$ is $\underline{\underline{Z}}$-torsion, since it is a cocyclic module. On the other hand, $Q / \underline{C}(Q)$ is a primitive quasimodule and thus $Q$ is $\mathbb{E}$-torsion. The rest is clear.
4.5 Example. Let $\alpha$ be an infinite limit ordinal number and $H=\left\{a_{0}, a_{1}, \ldots\right\}$ be the canonical basis of the vector space $Q=$ $\underline{Z}_{3}^{(\alpha)}$. Define a mapping $t$ of $H^{3}$ into $Q$ by $t\left(a_{\beta}, a_{\beta+1}, a_{\beta+2}\right)=$ $=a_{0}, t\left(a_{\beta+1}, a_{\beta}, a_{\beta+2}\right)=-a_{0}$ for $1 \leq \beta \leq \alpha$ and $t\left(a_{\beta}, a_{\gamma}, a_{\gamma}\right)=0$ in all romaining cases. It is clear that $t$ can be extended uniquely to a trilinear mapping $T$ of $Q^{3}$ into $Q$ such that $T(x, x, y)=T(T(x, y, z), u, v)=T(u, v, T(x, y, z))=T(u, T(x, y, z), v)=0$ for all $x, y, x, u, v \in Q$. Put $x * y=x+y+T(x, y, x-y)$ for all $x, y \in Q$. Then $Q^{\prime}=Q(*)$ is a primitive quasimodule nilpotent of clase 2 (see [m]). Moreover, $a \in \underline{C}\left(Q^{\prime}\right)$ iff $T(a, x, y)+$ $+T(x, y, a)+T(y, a, x)=0$ for all $x, y \in Q$. How it is easy to check that we have $\underline{G}\left(Q^{\prime}\right)=\underline{A}\left(Q^{\prime}\right)=\left\{0, a_{0},-a_{0}\right\}$. In particular, $Q^{\circ}$ is a cocyclic quasimodule. Thus for every infinite cardinal $\varepsilon$ there is a cocyclic primitive quasimodule (nilpotent of class 2) of cardinality $\varepsilon$.
4.6 Example. Let $n \geq 4, Q=\underline{z}_{3}^{(n)}, a_{1}=(1,0, \ldots, 0), \ldots, a_{n}=$
$=(0, \ldots, 0,1), N=\left\{a_{1}, \ldots, a_{n}\right\}$. Define a mapping $t$ of $H^{3}$ into $Q$ by $t\left(a_{i}, a_{i+1}, a_{i+2}\right)=a_{n}, t\left(a_{i+1}, a_{i}, a_{i+2}\right)=-a_{n}$ for every $1 \leq 1 \leq n-3, t\left(a_{n-2}, a_{n-1}, 1\right)=a_{n}, t\left(a_{n-1}, a_{n-2}, 1\right)=-a_{n}$, $t\left(a_{n-1}, 1,2\right)=a_{n}, t\left(1, a_{n-1}, 2\right)=-a_{n}$. Then $t$ can be extended uniquely to a trilinear mapping $T$ of $Q^{3}$ into $Q$ and we put $x * y=x+y+T(x, y, x-y)$. Then $Q^{\prime}=Q(*)$ is a primitive quasimodule nilpotent of class $2,\left|Q^{0}\right|=3^{n}$ and it is not difficult to check that $Q^{\prime}$ is cocyclic, provided $n \neq 5$ and $n \neq 6 k+1$. By [14], for every $m \geq 1, m \neq 2,3,5$, there is a cocyclic primitive quasimodule of order $3^{m}$, nilpotent of class 2. On the other hand, it is clear that there are no cocyclic primitive quasimodules of order $3^{2}, 3^{3}$ and it is proved in [8] that there is no cocyclic primitive quasimodule of order $3^{5}$.
5. Cohereditary radicals and varieties of quasimodules

By a variety of quasimodules we mean a noh-empty class of quasimodules closed under cartesian products, subquasimodules and homomorphic images.
5.1 Proposition. (i) If $q$ is a cohereditary radical then the class $v_{q}$ of all torsionfree quasimodules is a variety. (ii) Let $V$ be a variety of quasimodules. For every quasimodule $Q$, let $q_{V}(Q)=\cap \operatorname{Ker} f, f: Q \rightarrow P, P$ e $V$. Then $q_{V}$ is acohereditary radical.
(iii) The correspondence $q \rightarrow v_{q}$ and $v \rightarrow q_{v}$ between cohereditary radicals and varieties of quasimodules is bijective.

Proof. Easy.
Let $V$ be a variety of quasimodules. Denote by $V_{m}$ (resp. $V_{p}$ ) the class of all modules (resp. primitive quasimodules) contained in $V$ and put $L_{w}=a_{m}(R)$. Then both $v_{m}$ and $v_{p}$ - 713 -
are varieties, $I_{V}$ is an ideal of $\underline{R}, L_{v Q}=0$ for every quasimodule $Q$ e $V$ and a module $M$ belongs to $V{ }_{m}$ iff $L_{V} \mathbf{M}=0$.
5.2 Proposition. Let $v$ be a variety of quasimodules such that $L_{v} \not \equiv I$. Then $v=v_{m}$ and $v_{p}=0$.

Proof. We have $\underline{R}=I_{\gamma}+I$, so that $Q=\underline{R} Q=0$ for every $Q \cdot v_{p}$.
5.3 Proposition. Let $v$ be a variety of quasimodules and let $F$ e $v$ be a quasimodule free in $v$. Then $\underline{B}(F) \cap A(F)=0$. Proof. Let $X$ be a free basis of $F$ and let $f$ denote the natural homomorphism of $F$ onto $G=F / A(F)$. Then $G$ is a free $R / L_{V}$-module, $f \mid X$ is injective and $f(X)$ is a free basis of $G$. Now, let a $A(F) \cap \underline{B}(F)$. By 2.3 there are $n \geq 0$, pairwise different $x_{1}, \ldots, x_{n} \in X$ and elements $r_{1}, \ldots, r_{n} \in I$ with $a=r_{1} x_{1}+\ldots+r_{n} x_{n}$ (we have $r_{i} x_{i} \in \underline{C}(F)$ ). Consequently, $0=$ $=r_{1} f\left(x_{1}\right)+\ldots+r_{n} f\left(x_{n}\right), r_{1}, \ldots, r_{n} \in I$ and $a=0$. 5.4 Proposition. Let $v$ be variety of quasimodules. Then $V$ is just the variety generated by $v_{m} \cup V_{p}$.

Proof. This is an easy consequence of 5.3.
5.5 Proposition. Let $U$ and $U$ be varieties of modules and primitive quasimodules, respectively. Denote by $v$ the variety af
 Proof. Let $F e v$ be a free quasimodule of infinite countable rank. Since $V$ is generated by $U \cup W, F$ is isomorphic to a subquasimodule of the product $G \times P, G \in U$ and $P \in W$ being free of infinite countable rank; we shall assume that $F$ is a subquasimodule ${ }^{n} \times P$. Consequently, $I_{u} F=0$ and we
see that $U=v_{m}$. On the other hand, $B(F) \subseteq H=G \times 0$, $\underline{B}(F)$ is a normal subquasimodule of $G \times P$ and $F / \underline{B}(F)$ is isomorphic to a subquasimodule of $(H / B(F)) \times P \in W$. However, $\mathcal{V}_{p}$ is generated by $F / \underline{B}(F)$ and therefore $W=V_{p}$. Now, denote by $y$ the dual lattice of the lattice of idealf of the ring $\underline{R}$ and by $P$ the lattice of varieties of primitive quasimodules (i.e. the lattice of varieties of 3-elementary commutative Moufang loops). Let $\mathcal{L}$ be the subset of $y x p$ formed by all couples $(I, U)$, where either $U=0$, or $0 \neq$ $\neq U \neq U_{m}$ and $I \subseteq I$.
5.6 Theorem. The lattice of varieties of quasimodules is isomorphic to the lattice $\mathcal{L}$.

Proof. Apply 5.2, 5.4 and 5.5.
5.7 Proposition. Let $R$ be left noetherian, $n \geq 0$ and $v$ be a variety of quasimodules nilpotent of class at most $n$. Then $V$ is finitely based (i.e. $V$ can be determined by a finite number of identities).

Proof. Using $1.7(i i 1)$, we can proceed in the same way as in the proof of [6, Theorem III ].
5.8 Corollary. Let $R$ be left noetherian, $n \geq 0$ and $v$ be a variety of quasimodules nilpotent of class at most $n$. Then $v$ contains only countably many subvarieties.

By $[13, \S 10]$, the lattice of varieties of primitive quasimodules nilpotent of class at most 2 is a three-element chain. Having some information on the lattice of ideals of $R$ (e.g. 11 R is a commutative principal ideal ring, etc.) and using 5.6, we can describe the lattice of varieties of quasimodules nilpo-

```
tent of class at most 2 . Moreover, applying the methods deve-
loped in [7] for medial quasigroups, the results are transfer-
able to various classes of trimedial quasigroups (cf. 1.4).
