## ANTIDOMATIC NUMBER OF A GRAPH

BOHDAN ZELINKA

ABSTRACT. A subset  $D$  of the vertex set  $V(G)$  of a graph  $G$  is called dominating in  $G$ , if for each  $x \in V(G) - D$  there exists  $y \in D$  adjacent to  $x$ . An antidomatic partition of  $G$  is a partition of  $V(G)$ , none of whose classes is a dominating set in  $G$ . The minimum number of classes of an antidomatic partition of  $G$  is the number  $\bar{d}(G)$  of  $G$ . Its properties are studied.

In this paper we introduce a new numerical invariant of a graph, called antidomatic number. We consider finite undirected graphs without loops and multiple edges.

In [1] the domatic number of a graph was introduced. Let  $D$  be a subset of the vertex set  $V(G)$  of a graph  $G$ . The set  $D$  is called dominating in  $G$ , if for each  $x \in V(G) - D$  there exists a vertex  $y \in D$  adjacent to  $x$ . A partition of  $V(G)$ , all of whose classes are dominating sets in  $G$ , is called the domatic partition of  $G$ . The maximum number of classes of a domatic partition of  $G$  is called the domatic number of  $G$  and denoted by  $d(G)$ .

We introduce a similar concept; it was yet mentioned in [2]. If a subset  $A \subseteq V(G)$  is not dominating in  $G$ , we call it non-dominating in  $G$ . A partition of  $V(G)$ , all of whose classes are non-dominating sets in  $G$ , is called an antidomatic partition of  $G$ . The minimum number of classes of an antidomatic partition of  $G$  is called the antidomatic number of  $G$  and denoted by  $\bar{d}(G)$ .

**Proposition 1.** *The antidomatic number of a graph  $G$  is well-defined if and only if  $G$  has no saturated vertex, i.e. vertex adjacent to all others.*

Namely, a graph containing a saturated vertex  $v$  has no antidomatic partition, because each subset of its vertex set which contains  $v$  is dominating.

**Proposition 2.** *For every graph  $G$  without saturated vertices*

$$\bar{d}(G) \geq 2.$$

This follows from the fact that the set  $V(G)$  is dominating in  $G$  (and thus not non-dominating).

The antidomatic number of a graph is closely related to its diameter.

---

1991 *Mathematics Subject Classification*: 05C35.

*Key words and phrases*: dominating set, antidomatic partition, antidomatic number.

Received March 23, 1994.

**Theorem 1.** *Let  $G$  be a graph without saturated vertices. The antidomatic number  $\bar{d}(G) = 2$  if and only if  $\text{diam } G \geq 3$ .*

**Proof.** Suppose  $\text{diam } G \geq 3$ . Let  $x, y$  be two vertices whose distance in  $G$  is at least 3. (This includes the case when this distance is  $\infty$ , i.e. when no path connects  $x$  and  $y$  in  $G$ .) Let  $A_1$  be the set consisting of  $x$  and of all vertices which are adjacent to  $x$  in  $G$ , let  $A_2 = V(G) - A_1$ . The set  $A_1$  is not dominating in  $G$ , because  $y \in V(G) - A_1$  and is adjacent to no vertex of  $A_1$ . The set  $A_2$  is not dominating in  $G$ , because  $x \in V(G) - A_2$  and is adjacent to no vertex of  $A_2$ . Therefore  $\{A_1, A_2\}$  is an antidomatic partition of  $G$  and  $\bar{d}(G) = 2$ .

Now suppose  $\bar{d}(G) = 2$  and let  $\{B_1, B_2\}$  be an antidomatic partition of  $G$ . As  $B_1$  (or  $B_2$ ) is not dominating in  $G$ , there exists a vertex  $u_2 \in B_2$  (or  $u_1 \in B_1$ ) which is adjacent to no vertex of  $B_1$  (or  $B_2$  respectively). Obviously  $u_1, u_2$  are not adjacent and their distance is not 1. If this distance were 2, there would exist a vertex  $v$  adjacent to both  $u_1, u_2$ . But  $v$  might be neither in  $B_1$ , nor in  $B_2$ , which would be a contradiction. Hence the distance between  $u_1$  and  $u_2$  is at least 3 and  $\text{diam } G \geq 3$ .  $\square$

Therefore at the study of  $d(G)$  we may restrict ourselves to graphs with  $\text{diam } G = 2$ .

Now we relate  $d(G)$  to degrees of vertices of  $(G)$ .

**Theorem 2.** *Let  $G$  be a graph without saturated vertices, let  $n$  be its number of vertices, let  $\delta(G)$  be the minimum degree of a vertex in  $G$ . Then*

$$\lceil (n/(n-1) - \delta(G)) \rceil \leq \bar{d}(G) \leq \delta(G) + 2$$

**Proof.** Let  $A \subseteq V(G)$  be a non-dominating set in  $G$ . Then there exists at least one vertex  $x \in V(G) - A$  which is adjacent to no vertex of  $A$ . The degree of  $x$  in  $G$  is at most  $n - 1 - |A|$ . We have  $n - 1 - |A| \geq \delta(G)$ , which implies  $|A| \leq n - 1 - \delta(G)$ . Every antidomatic partition of  $G$  has the property that each of its classes has at most  $n - 1 - \delta(G)$  elements and this implies the first inequality.

Now let  $u$  be a vertex of  $G$  having the degree  $\delta(G)$ . Let  $v_1, \dots, v_\delta$  be the vertices adjacent to  $u$ , let  $A = V(G) - \{u, v_1, \dots, v_\delta\}$ . As  $G$  has no saturated vertex,  $A \neq \emptyset$ . The set  $A$  is not dominating in  $G$ , because  $u \in V(G) - A$  and is adjacent to no vertex of  $A$ . No vertex is saturated, therefore no one-element set is dominating in  $G$ . The partition  $\{\{u\}, \{v_1\}, \dots, \{v_\delta\}, A\}$  is an antidomatic partition of  $G$  with  $\delta(G) + 2$  vertices, which implies the second inequality.  $\square$

**Corollary.** *Let  $G$  be a graph without saturated vertices, let  $n$  be its number of vertices, let  $\bar{d}(G) = n$ . Then  $n$  is even and  $G$  is obtained from the complete graph  $K_n$  by deleting edges of a linear factor.*

The Zykov sum  $G_1 \oplus G_2$  of two graphs  $G_1, G_2$  is the graph obtained from disjoint graphs  $G_1, G_2$  by joining each vertex of  $G_1$  with each vertex of  $G_2$  by an edge.

The following lemma is easy to prove.

**Lemma.** *Let  $G_1, G_2$  be graphs without saturated vertices. Then*

$$\bar{d}(G_1 \oplus G_2) = \bar{d}(G_1) + \bar{d}(G_2) .$$

If  $G$  is a graph, then  $\bar{G}$  denotes the complement of  $G$ .

**Theorem 3.** *Let  $k, n$  be integers such that  $2 \leq k \leq n - 2$ . Then there exists a graph  $G$  with  $n$  vertices such that  $d(G) = k$ .*

**Proof.** If  $k$  is even, then  $G$  is the Zykov sum of  $\frac{1}{2}k - 1$  copies of  $\bar{K}_2$  and one copy of  $\bar{K}_{n-k+2}$ . If  $k$  is odd, then  $G$  is the Zykov sum of  $\frac{1}{2}(k - 1) - 3$  copies of  $\bar{K}_2$ , one copy of  $C_5$  and one copy of  $\bar{K}_{n-k}$ . Here  $C_5$  denotes the circuit of length 5; its is easy to see that  $\bar{d}(C_5) = 3$ .  $\square$

**Theorem 4.** *Let  $n$  be an integer,  $n \geq 2$ . The graph  $G$  with  $n$  vertices and  $\bar{d}(G) = n$  exists if and only if  $n$  is even. The graph  $H$  with  $n$  vertices and  $\bar{d}(H) = n - 1$  exists if and only if  $n$  is odd.*

**Proof.** The graph  $G$  is described in Corollary; it is the Zykov sum of  $\frac{1}{2}n$  copies of  $\bar{K}_2$ . The graph  $H$  is the Zykov sum of  $\frac{1}{2}(n - 3)$  copies of  $\bar{K}_2$  and one copy of  $\bar{K}_3$  (or one copy of  $\bar{P}_2$ , where  $P_2$  is a path of length 2).

Now we shall prove that the graph  $G$  for  $n$  odd does not exist. Consider a graph  $G$  with required properties. The unique antidomatic partition of  $G$  is the partition of  $V(G)$  into one-element sets. Every subset of  $V(G)$  having more than one vertex is dominating. This implies that the degree of each vertex must be  $n - 2$ . It is possible only if  $n$  is even.

We shall prove that the graph  $H$  for  $n$  even does not exist. Consider a graph  $H$  with required properties. Evidently  $H$  has no non-dominating set with more than two vertices (and thus  $\delta(H) = n - 3$ ) and no two disjoint non-dominating sets with two vertices. It has at least one non-dominating set with two vertices; otherwise its antidomatic number would be  $n$ . If  $H$  contains exactly one non-dominating set with two vertices, then it has exactly one vertex of degree  $n - 3$  and all others of degree  $n - 2$ ; this is possible only if  $n$  is odd. Now suppose that  $H$  has two non-dominating sets which are not disjoint. Let them be  $\{x, y\}, \{y, z\}$ , where  $x, y, z$  are pairwise distinct. Let  $u$  be a vertex not contained in  $\{x, y\}$  and not adjacent to any vertex of  $\{x, y\}$ ; let  $v$  be an analogous vertex for  $\{y, z\}$ . If  $u = v$ , then  $\{x, y, z\}$  is a non-dominating set with three vertices, which is impossible. If  $u \neq v$ , then  $\{u, v\}$  is another non-dominating set with two vertices, because  $y$  is adjacent neither to  $u$ , nor to  $v$ . It may not be disjoint with  $\{x, y\}$  or with  $\{y, z\}$  and this is possible only if  $u = z, v = x$ . Then the subgraph of  $G$  induced by  $\{x, y, z\}$  is  $\bar{K}_3$  and  $H = H_0 \oplus \bar{K}_3$ , where  $H_0$  is the graph obtained from  $H$  deleting  $x, y, z$ . As  $\bar{d}(H) = n - 1, \bar{d}(\bar{K}_3) = 2$ , we have  $\bar{d}(H_0) = n - 3$  and this is also its number of vertices. Such an equality is possible only if  $n - 3$  is even, i.e. if  $n$  is odd.  $\square$

**Theorem 5.** *Let  $G$  be a graph without saturated vertices, let  $\chi(G)$  be its chromatic number. Then*

$$d(G) \leq 2\chi(G) .$$

*This bound is sharp.*

**Proof.** Let  $\chi(G) = h$ . Suppose that  $G$  is coloured by  $n$  colours  $1, \dots, h$  and let  $B_i$  be the set of vertices coloured by the colour  $i$  for  $i = 1, \dots, h$ . We shall construct an antidomatic partition of  $G$ . If a set  $B_i$  is non-dominating in  $G$ , then it will be a class of this partition. If  $B_i$  is dominating in  $G$ , then it has at least two elements, because no saturated vertices exist. We choose an arbitrary partition  $\{B'_i, B''_i\}$  of  $B_i$  into two classes; the sets  $B'_i, B''_i$  (evidently non-dominating in  $G$ ) will be classes of the constructed partition. The resulting antidomatic partition has at most  $2\chi(G)$  classes, which implies the inequality. If  $G$  is a complete  $h$ -partite graph, then non-dominating sets are only proper subsets of its parties, therefore the equality occurs.  $\square$

**Corollary 2.** *Let  $G$  be a bipartite graph different from a star. If  $G$  is a complete bipartite graph, then  $\bar{d}(G) = 4$ ; otherwise  $\bar{d}(G) = 2$ .*

**Theorem 6.** *Let  $G$  be a graph without saturated vertices, let  $\gamma(G)$  be its dominating number. Then*

$$\bar{d}(G) \leq n/(\gamma(G) - 1).$$

**Proof.** The domination number  $\gamma(G)$  is the minimum number of vertices of a dominating set in  $G$ . There exists a partition of  $V(G)$  into  $n/(\gamma(G) - 1)$  classes, each of which has at most  $\gamma(G) - 1$  vertices and hence is non-dominating. This implies the assertion.  $\square$

At the end we shall study regular graphs of degree  $n - 3$ , where  $n$  is the number of vertices. Such a graph is a complement of a regular graph of degree 2 and this is a graph whose connected components are circuits. Hence a regular graph of degree  $n - 3$  is either a complement of a circuit, or a Zykov sum of complements of circuits. Therefore we determine  $\bar{d}(\bar{C}_n)$ , where  $C_n$  is a circuit of length  $n$ .

**Theorem 7.** *Let  $C_n$  be a circuit of length  $n$ , let  $\bar{C}_n$  be its complement. Then*

$$\begin{aligned} \bar{d}(\bar{C}_n) &= n/2 && \text{for } n \equiv 0 \pmod{4}, \\ \bar{d}(\bar{C}_n) &= n/2 + 1 && \text{for } n \equiv 2 \pmod{4}, \\ \bar{d}(\bar{C}_n) &= (n + 1)/2 && \text{for } n \text{ odd.} \end{aligned}$$

**Proof.** The graph  $\bar{C}_n$  is a regular graph of degree  $n - 3$ ; by Theorem 3 we have  $\bar{d}(\bar{C}_n) \geq \lceil n/2 \rceil$  and this is  $\bar{d}(\bar{C}_n) \geq n/2$  for  $n$  even and  $\bar{d}(\bar{C}_n) \geq (n + 1)/2$  for  $n$  odd. Let  $u_1, \dots, u_n$  be the vertices of  $C_n$  and let  $u_i u_{i+1}$  for  $i = 1, \dots, n - 1$  and  $u_n u_1$  be the edges of  $C_n$ . If  $n \equiv 0 \pmod{4}$ , we take  $n/2$  sets  $\{u_{4i+1}, u_{4i+3}, u_{4i+2}, u_{4i+4}\}$  for  $i = 0, \dots, n/4 - 1$ ; this is an antidomatic partition of  $\bar{C}_n$  into  $n/2$  classes and  $\bar{d}(\bar{C}_n) = n/2$ . If  $n \equiv 1 \pmod{4}$  we take the sets  $\{u_{4i+1}, u_{4i+3}\}, \{u_{4i+2}, u_{4i+4}\}$  for  $i = 0, \dots, (n - 1)/4 - 1$  and the sets  $\{u_n\}$ . For  $n \equiv 3 \pmod{4}$  we take the sets  $\{u_{4i+1}, u_{4i+3}\}, \{u_{4i+2}, u_{4i+4}\}$  for  $i = 0, \dots, (n - 3)/4 - 1$  and the sets  $\{u_{n-2}, u_n\}, \{u_{n-1}\}$ . In both these cases we have an antidomatic partition with  $(n + 1)/2$  classes

and  $d(C_n) = \lceil (n+1)/2 \rceil$ . Now the case  $n \equiv 2 \pmod{4}$  remains. Suppose that there exists an antidomatic partition  $A$  consisting only of two-element sets. Each of them has the form  $\{u_i, u_{i+2}\}$ , where  $i+2$  is taken modulo 2. Let  $U_1$  (or  $U_2$ ) be the set of all vertices  $u_i$  (or  $u_{i+2}$  respectively) such that  $\{u_i, u_{i+2}\} \in A$ . Evidently  $\{U_1, U_2\}$  is a partition of  $V(C_n)$  and  $|U_1| = |U_2| = \frac{1}{2}n$ . No two vertices of  $U_1$  can have the distance 2 in  $C_n$  and thus at least two of them are adjacent; without loss of generality let  $u_1 \in U_1, u_2 \in U_1$ . For  $j \in \{0, 1, 2, 3\}$  let  $N_j$  be the set of numbers from  $\{1, \dots, n\}$  which are congruent to  $j$  modulo 4. Let  $f$  be a permutation of  $\{1, \dots, n\}$  such that for  $i = 1, \dots, n$  the value  $f(i)$  is such a number  $j$  that  $j \equiv i$  and  $\{u_i, u_j\} \in A$ . Then  $f$  maps bijectively  $N_0$  onto  $N_2, N_1$  onto  $N_3, N_2$  onto  $N_0, N_3$  onto  $N_1$ . But  $|N_0| = (n-2)/4, |N_2| = (n-2)/4 + 1$ , which is a contradiction. Therefore  $\bar{d}(C_n) \geq n+1$ . We take the sets  $\{u_{i+1}, u_{4i+3}\}, \{u_{4i+2}, u_{4i+4}\}$  for  $i = 0, \dots, n/2 - 2$  and the sets  $\{u_{n-1}\}, \{u_n\}$ ; this is an antidomatic partition of  $C_n$  and  $\bar{d}(C_n) = n/2 + 1$ .

For circuits themselves the values are clear:  $\bar{d}(C_4) = 4, \bar{d}(C_5) = 3, \bar{d}(C_n) = 2$  for  $n \geq 6$ .
