COUPLED FIXED POINTS OF MIXED MONOTONE OPERATORS ON PROBABILISTIC BANACH SPACES

ISMAT BEG, ABDUL LATIF, RASHID ALI, AKBAR AZAM

Abstract. The existence of minimal and maximal fixed points for monotone operators defined on probabilistic Banach spaces is proved. We obtained sufficient conditions for the existence of coupled fixed point for mixed monotone condensing multivalued operators.

1. Introduction and Preliminaries

In his seminal paper Menger [11] introduced the notion of probabilistic metric space, which is a generalization of the metric space. The study of these spaces was extensively performed by Schweizer and Sklar [12, 13] and many other authors [4, 7, 14, 18]. The theory of probabilistic metric/normed spaces is of fundamental importance in probabilistic functional analysis. Recently a number of fixed point theorems and their applications in probabilistic metric spaces have been proved by several authors; Beg, Rehman and Shahzad [1], Bharucha-Reid [2], Cain and Kasriel [3], Hadzic [8], Stojakovic [15, 16] and others [5, 19]. In this paper, we introduce mixed monotone operators in probabilistic Banach spaces by defining a suitable ordering in these spaces and proved the existence of coupled minimal and maximal fixed points for these operators. The results obtained are probabilistic analogue of the results of [6, 9] and [17].

Let $\mathbb{R}$ denotes the set of real numbers and $\mathbb{R}^+ = \{x \in \mathbb{R} : x \geq 0\}$. A mapping $f : \mathbb{R} \to \mathbb{R}^+$ is called a distribution function if it is nondecreasing, left continuous with $\inf_{x \in \mathbb{R}} f(x) = 0$ and $\sup_{x \in \mathbb{R}} f(x) = 1$. We will denote by $\mathcal{L}$ the set of all distribution functions.

**Definition 1.1** [4]. Let $E$ be a vector space over the field $\mathbb{R}$. Let $\| ; \|$ be a mapping on $E$ with values in $\mathcal{L}$. For each $p \in E$ the distribution function $\| ; \|(p)$ will be denoted by $\|p; \|$ and the value of $\| ; \|(p)$ at $t \in \mathbb{R}$ will be denoted by $\|p; t\|$. The function $\| ; \|$ is assumed to satisfy the following conditions:

---

2000 Mathematics Subject Classification: 47H07, 47H10, 47H04, 46S50.
Key words and phrases: probabilistic Banach space, monotone operator, fixed point.
Received September 14, 1999.
bounded if the cone interval and is denoted by \( \| x \| \). Let \( x \) and only if
\[ \| x \| = H \] where \( H \) is a distribution function defined by
\[ H(t) = \begin{cases} 0 & \text{if } t \leq 0 \\ 1 & \text{if } t > 0. \end{cases} \]

(PN2) For every \( p \in E, \ t \in \mathbb{R}^+ \) and \( \lambda \in \mathbb{R} - \{0\} \)
\[ \| \lambda p; t \| = \| p; \frac{t}{|\lambda|} \|. \]

(PN3) If \( \| p; t_1 \| = 1, \| q; t_2 \| = 1 \), then
\[ \| p + q; t_1 + t_2 \| = 1 \]
for all \( p, q \in E \) and \( t_1, t_2 > 0 \).

The mapping \( p \to \| p; \| \) is called the probabilistic norm on \( E \) and \( E \) together with this norm is called probabilistic normed space (or simply a PN-space). The PN-space \( (E, \| ; \|) \) becomes a PM-space under the probabilistic metric \( F : E \times E \to \mathcal{L} \) defined by \( F(p, q) = \| p - q; \|. \) For detailed discussion on probabilistic normed spaces, we refer to [4, 5, 13, 18].

Let \( (E, \| ; \|) \) be a PN-space. Then a neighbourhood of an element \( p \in E \), is defined by the set: \( U_p(\epsilon, \lambda) = \{ q \in E : \| p - q; \epsilon \| > 1 - \lambda \} \), where \( \epsilon > 0, \lambda \in (0, 1) \).

**Definition 1.2.** Let \( (E, \| ; \|) \) be a PN-space and \( A \) be a nonempty subset of \( E \). The probabilistic diameter of \( A \) is a function \( D_A \), defined on \( \mathbb{R}^+ \) by \( D_A(t) = \sup_{s<\lambda} \inf_{p,q \in A} \| p - q; s \| \). A subset \( A \) of a PN-space is said to be bounded if \( \sup_{t>0} D_A(t) = 1 \).

**Definition 1.3** [13]. Let \( \mu : \mathcal{L} \times \mathcal{L} \to \mathcal{L} \) be a triangle function. A probabilistic normed space under a triangle function \( \mu \) is a triple \( (E, \| ; \|, \mu) \) satisfying PN1, PN2 and \( \mu \) satisfies the following condition for any \( t \in \mathbb{R} \):

(PN4) \[ \| p + q; t \| \geq \mu(\| p; t \|, \| q; t \|) = \mu(\| p; \|, \| q; \|)(t). \]

**Definition 1.4.** Let \( E \) be a probabilistic Banach space. A subset \( P \subset E \) is a cone if and only if it satisfies the following conditions:

(i) \( P \) is closed and convex;

(ii) if \( p \in P, \ tp \in P \) for every \( t \geq 0 \);

(iii) if both \( p \) and \( -p \) are in \( P \), then \( p = 0 \).

The order “\( \leq \)” is introduced by the cone \( P \) in \( E \). That is, \( p, q \in E, p \leq q \) if and only if \( p - q \in P \). Thus \( E \) becomes a partially ordered probabilistic Banach space. Let \( E \) be a partially ordered probabilistic Banach space, \( x, y \in E \) and \( x \leq y \). A cone \( P \) is said to be normal if and only if there is some \( m > 0 \) such that
\[ \| x; t \| \geq \| y; \frac{t}{m} \|, \quad t \in \mathbb{R} \]

Let \( u, v \in E \). The set of element \( x \in E \) such that \( u \leq x \leq v \) is called an ordered interval and is denoted by \( [u, v] \). An ordered interval is closed and convex. It is bounded if the cone \( P \) is normal.
Definition 1.5. Let $D$ be a subset of $E$. An operator $A : D \times D \to E$ is said to be mixed monotone if for each fixed $y \in D$, $A(x, y)$ is nondecreasing in $x$ and for each fixed $x \in D$, $A(x, y)$ is nonincreasing in $y$.

2. The Results

Throughout this section the probabilistic Banach space $(E, \|\cdot\|)$ will be denoted by $E$, which is partially ordered by a cone $P$ in $E$.

Definition 2.1. Let $D$ be a subset of $E$ and $A : D \times D \to E$ be an operator:

(a) If $x, y \in D$ with $x \leq y$ can be found such that $x \leq A(x, y)$ and $A(y, x) \leq y$, then $(x, y)$ is called a coupled lower and upper fixed point of $A$.

(b) If $x, y \in D$ with $x \leq y$ can be found such that $x = A(x, y)$ and $A(y, x) = y$, then $(x, y)$ is called coupled fixed point of $A$. If a coupled fixed point $(x^*, y^*)$ can be found such that $x^* \leq x$ and $y \leq y^*$ for every coupled fixed point $(x, y)$ of $A$, then $(x^*, y^*)$ is called the minimal and maximal fixed point of $A$.

(c) A point $x^* \in D$ is a fixed point of $A$ if

$$A(x^*, x^*) = x^*.$$ 

A sequence $\{x_n\}$ in $E$ is said to be monotone increasing (decreasing) if and only if $x_{n-1} \leq x_n$ ($x_{n-1} \geq x_n$) for all $n$. The operator $A$ is called compact if for every bounded subset $D_1 \subset D$, $A(D_1 \times D_1)$ is relatively compact. We now state the following standard lemma whose proof is routine.

Lemma 2.2. Let $P$ be a cone in the probabilistic Banach space $E$. Let $D$ be a subset of $E$ and $A : D \times D \to E$ be mixed monotone operator. Assume that there is an ordered interval $[u, v] \subset D$ such that $(u, v)$ is a coupled lower and upper fixed point of $A$. Then:

(i) $A$ maps $[u, v] \times [u, v]$ into $[u, v]$;

(ii) the sequences $\{x_n\}, \{y_n\}$ defined by setting $x_0 = u$, $y_0 = v$ and $x_n = A(x_{n-1}, y_{n-1})$, $y_n = A(y_{n-1}, x_{n-1})$ for $n \geq 1$ are monotone increasing and decreasing respectively.

Theorem 2.3. Let $P$ be a cone in the probabilistic Banach space $E$. Let $D$ be a subset of $E$ and $A : D \times D \to E$ be continuous and mixed monotone operator. Assume that there is an ordered interval $[u, v] \subset D$ such that $(u, v)$ is a coupled lower and upper fixed point of $A$. Then $A$ has a coupled fixed point in $[u, v] \times [u, v]$ if $P$ is normal and $A$ is compact.
Theorem 2.5. Let \( E \) be a probabilistic Banach space under the triangle function \( \mu \) with \( \mu = \inf \) and \( 0 < k < 1 \). Let \( u, v \in E \) with \( u \leq v \) and \( D = [u, v] \). Suppose that \( A : D \times D \to E \) is an operator satisfying all the assumptions in Theorem 2.4, and also satisfies the following conditions:

(iii) For any fixed \( x \in D \) and \( t \in \mathbb{R} \)

\[
\|A(u, x) - A(v, x); t\| > \|u - v; t\| \quad \text{for all } u, v \in D;
\]

(iv) for any fixed \( y \in D \) and \( t \in \mathbb{R} \)

\[
\|A(y, u) - A(y, v); t\| > \|u - v; t\| \quad \text{for all } u, v \in D.
\]

Then \( A \) has a unique fixed point \( u^* \) in \( D \), and \( x* = u^* = y^* \), where \((x^*, y^*)\) is a coupled minimal and maximal fixed point of \( A \) in \( D \).
Proof. From Theorem 2.4, it follows that \( A \) has a coupled minimal and maximal fixed point \((x^*, y^*)\) in \( D \). So it suffices to show that \( x^* = y^* \). For this, let us assume the contrary, that is, \( x^* \neq y^* \). By using condition (iii) and (iv) we get

\[
\|x^* - y^*; t\| = \|A(x^*, y^*) - A(y^*, x^*); t\| \\
= \|A(x^*, y^*) - A(x^*, x^*) + A(x^*, x^*) - A(y^*, x^*); t\| \\
\geq \mu (\|A(x^*, y^*) - A(x^*, x^*); t\|, \|A(x^*, x^*) - A(y^*, x^*); t\|) \\
> \mu (\|y^* - x^*; t\|, \|x^* - y^*; t\|) \\
= \|x^* - y^*; t\| \\
\geq \|x^* - y^*; t\|,
\]

which is a contradiction. So \( x^* = y^* \) and \( u^* = x^* = y^* \) is a fixed point of \( A \). The uniqueness of \( u^* \) in \( D \) follows from the fact that the set of coupled fixed points of \( A \) is a subset of \([x^*, y^*]\). \(\Box\)

Definition 2.6. Let \( D \) be a subset of a probabilistic Banach space \( E \), which is partially ordered by a cone \( P \) of \( E \), and \( A : D \times D \to 2^E \) (the set of all subsets of \( E \)) a multivalued mapping. The operator \( A \) is said to be mixed monotone, if \( A(x, y) \) is nondecreasing in \( x \) and nonincreasing in \( y \), that is,

(i) for each \( y \in D \) and any \( x_1, x_2 \in D, x_1 \leq x_2 \) \((x_1 \geq x_2)\), if \( u_1 \in A(x_1, y) \) then there exists a \( u_2 \in A(x_2, y) \) such that \( u_1 \leq u_2 \) \((u_1 \geq u_2)\);

(ii) for each \( x \in D \) and any \( y_1, y_2 \in D, y_1 \leq y_2 \) \((y_1 \geq y_2)\), if \( v_1 \in A(x, y_1) \) then there exists a \( v_2 \in A(x, y_2) \) such that \( v_1 \geq v_2 \) \((v_1 \leq v_2)\).

A point \((x^*, y^*) \in D \times D \) is called coupled fixed point of \( A \), if

\[ x^* \in A(x^*, y^*), \quad y^* \in A(y^*, x^*). \]

Definition 2.7. An operator \( A : D \times D \to 2^E \) is said to be probabilistically condensing if for any \( D_1, D_2 \subset D \) either \( \alpha_{D_1} \) or \( \alpha_{D_2} \) is smaller than \( H \), then

\[ \alpha_{A(D_1, D_2)}(t) > \min \{ \alpha_{D_1}(t), \alpha_{D_2}(t) \}, \]

where \( \alpha_{D_i} \) is probabilistic Kuratowski measure of noncompactness of \( D_i \,(i = 1, 2) \).

For more details regarding probabilistic Kuratowski measure of noncompactness we refer to Istratescu [10].

Remark 2.8. For continuity of multivalued operators in case of PN-spaces, we can easily modify the Definition 10.2.3 of [10].

Theorem 2.9. Let \( E \) be a probabilistic Banach space. Let \( u_0, v_0 \in E \) and \( D = [u_0, v_0] \). Let \( A : D \times D \to 2^D \) be a continuous mixed monotone multivalued operator with nonempty closed values. Suppose that \( A \) is probabilistically condensing operator and \([u_0, v_0]\) is bounded. Then \( A \) has a coupled fixed point \((x^*, y^*)\) in \( D \times D \) and \( x^* = \lim_{n \to \infty} u_n, \ y^* = \lim_{n \to \infty} v_n \), where \( u_n \in A(u_{n-1}, v_{n-1}) \) and \( v_n \in A(v_{n-1}, u_{n-1}) \), satisfy the following condition:

\[ u_0 \leq u_1 \leq \ldots \leq u_n \leq \ldots; \quad v_0 \geq v_1 \geq \ldots \geq v_n \geq \ldots, \]
and if \( u_{n+1} = u_n, \ v_{n+1} = v_n \), then \( u_{n+k} = u_n \) and \( v_{n+k} = v_n \) where \( k = 1, 2, \ldots \).

**Proof.** If \( u_0 \in A(u_0, v_0) \) and \( v_0 \in A(v_0, u_0) \), take \( x^* = u_n = u_0 \) and \( y^* = v_n = v_0 \) \((n = 1, 2, \ldots)\), then the conclusion of the theorem is proved. Otherwise, taking \( u_1 \in A(u_0, v_0) \subset [u_0, v_0] \) then \( v_0 \geq u_1 \) and \( v_1 \leq v_0 \). If \( u_1 \in A(u_1, v_1), v_1 \in A(v_1, u_1) \), take \( x^* = u_n = u_1, \ y^* = v_n = v_1 \) \((n = 2, 3, \ldots)\), then the conclusion of theorem is proved; otherwise, by the mixed monotonicity of \( A \), since \( u_1 \in A(u_1, v_1), v_1 \in A(v_1, u_1) \) and \( u_0 \leq u_1, \ v_1 \leq v_0 \), there exist

\[
u_2 \in A(u_1, v_1) \text{ such that } u_1 \leq u_2
\]

and

\[
u_2 \in A(v_1, u_1) \text{ such that } v_2 \leq v_1.
\]

Choose \( u_k \in A(u_{k-1}, v_{k-1}), v_k \in A(v_{k-1}, u_{k-1}) \), such that \( u_{k-1} \leq u_k, v_{k-1} \geq v_k \). If \( u_k \in A(u_k, v_k), v_k \in A(v_k, u_k) \), then take \( x^* = u_n = u_k, \ y^* = v_n = v_k \) \((n = k + 1, k + 2, \ldots)\). Otherwise, by the mixed monotonicity of \( A \), there exist \( u_{k+1} \in A(u_k, v_k), v_{k+1} \in A(v_k, u_k) \) such that

\[ u_k \leq u_{k+1}, \ v_k \geq v_{k+1}. \]

Repeating this process, either the conclusion of theorem is proved, or we can obtain a nondecreasing sequence and a nonincreasing sequence as follows:

\[ u_0 \leq u_1 \leq \ldots \leq u_n \leq \ldots; \ v_0 \geq v_1 \geq \ldots \geq v_n \geq \ldots. \]

Letting \( D_1 = \{u_n\}, \ D_2 = \{v_n\}, \ (n = 0, 1, 2, \ldots) \), then \( D_1 \subset A(D_1, D_2) \cup \{u_0\}, \ D_2 \subset A(D_2, D_1) \cup \{v_0\} \). By the properties of Kuratowski probabilistic measure \( \alpha_{D_1} \) of noncompactness (for detailed properties of Kuratowski probabilistic measure \( \alpha_{D_1} \) of noncompactness see [10, Theorem 11.3.2])

\[
\alpha_{D_1}(t) \geq \min\{\alpha_{A(D_1,D_2)}(t), \alpha_{\{u_0\}}(t)\}
\]

\[
= \min\{\alpha_{A(D_1,D_2)}(t), H(t)\}
\]

\[
= \alpha_{A(D_2,D_1)}(t).
\]

Similarly \( \alpha_{D_2}(t) \geq \alpha_{A(D_1,D_2)}(t) \). If either \( \alpha_{D_1} \) or \( \alpha_{D_2} \) is smaller than \( H \), then by the condensing condition of \( A \),

\[
\alpha_{A(D_1,D_2)}(t) > \min\{\alpha_{D_1}(t), \alpha_{D_2}(t)\}
\]

and

\[
\alpha_{A(D_2,D_1)}(t) > \min\{\alpha_{D_2}(t), \alpha_{D_1}(t)\}.
\]

Therefore

\[
\alpha_{D_1}(t) > \min\{\alpha_{D_1}(t), \alpha_{D_2}(t)\}, \alpha_{D_2}(t) \} > \min\{\alpha_{D_2}(t), \alpha_{D_1}(t)\}.
\]

Hence \( \min\{\alpha_{D_1}(t), \alpha_{D_2}(t)\} > \min\{\alpha_{D_2}(t), \alpha_{D_1}(t)\} \), a contradiction. This shows that we must have \( \alpha_{D_1}(t) = \alpha_{D_2}(t) = H(t) \) for each \( t \in \mathbb{R} \) Istratescu [10, Theorem 11.3.5] further implies that set associated to both the sequences \( \{u_n\} \) and \( \{v_n\} \) are precompact. Therefore there exist convergent subsequences \( \{u_{n_k}\}, \{v_{n_k}\} \) of \( \{u_n\} \) and \( \{v_n\} \) respectively such that

\[
\lim_{k \to \infty} u_{n_k} = x^* \in [u_0, v_0], \ \lim_{k \to \infty} v_{n_k} = y^* \in [u_0, v_0].
\]
Let $\lim_{n \to \infty} u_n \neq x^*$. Then there exists $\epsilon_0 > 0$ and $\lambda_0 \in (0, 1)$ and a subsequence \{u'_{n_i}\} of \{u_n\} such that
\[
\|u'_{n_i} - x^*; \epsilon_0\| \leq 1 - \lambda_0.
\]
By the precompactness of \{u_n\}, there is a subsequence \{u'_{n_{i,j}}\} of \{u'_{n_i}\} such that $\lim_{j \to \infty} u'_{n_{i,j}} = x'$. Hence for any given $k$ it follows from the nondecreasingness of \{u_n\} that when $j$ is large enough
\[
u_{nk} \leq u'_{n_{i,j}}.
\]
First letting $j \to \infty$ and then letting $k \to \infty$ we have $x^* \leq x'$. Similarly we can also prove that $x' \leq x^*$. Hence $x' = x^*$. It follows that when $j$ is large enough
\[
\|u'_{n_{i,j}} - x^*; \epsilon_0\| > 1 - \lambda_0.
\]
This contradicts $\|u'_{n_{i,j}} - x^*; \epsilon_0\| \leq 1 - \lambda_0$ (for all $i$). Hence $\lim_{n \to \infty} u_n = x^*$. Similarly it can be proved that $\lim_{n \to \infty} v_n = y^*$. Since $u_n \in A(u_{n-1}, v_{n-1})$ and $v_n \in A(v_{n-1}, u_{n-1})$, it follows by the continuity of $A$ that $x^* \in A(x^*, y^*)$ and $y^* \in A(y^*, x^*)$. Thus $(x^*, y^*)$ is a coupled fixed point of $A$.

**Corollary 2.10.** Let all the conditions of Theorem 2.8 and the following condition be satisfied: for any $x_1 \leq x_2$, $y_1 \geq y_2$, $(x_1, y_1) \neq (x_2, y_2)$ and any $u \in A(x_1, y_1)$ and any $v \in A(x_2, y_2)$, $u \leq v$. Then
\[
u_n \leq x^* \leq y^* \leq v_n,
\]
and the coupled fixed point $(x^*, y^*)$ is minimal and maximal in the sense that for any coupled fixed point $(\bar{x}, \bar{y}) \in D \times D$ of $A$,
\[
x^* \leq \bar{x} \leq y^*, \quad x^* \leq \bar{y} \leq y^*.
\]
