FUNDAMENTAL VECTOR FIELDS ON ASSOCIATED FIBER BUNDLES

IVAN KOLÁŘ, Brno

(Received February 18, 1977)

If G is a Lie groupoid and Y is a fiber bundle associated with G , then every section of the Lie algebroid LG of G determines a vector field on Y , which we call a *fundamental vector field* on Y . After deducing certain basic properties, we study the prolongations of the fundamental vector fields in connection with the general prolongation theory of projectable vector fields on arbitrary fibered manifolds, [2], [4], and with the prolongation theory of Lie algebroids, [5], [6]. We also develop a general point of view to Lie differentiation. Our consideration is in the category C^∞ .

1. Given two manifolds M, N and diffeomorphisms $\varphi : M \rightarrow M, \psi : N \rightarrow N$, we define an induced diffeomorphism $(\varphi, \psi)^r$ on the space $J^r(M, N)$ of all r -jets of M into N by

$$(1) \quad j_x^r f \mapsto j_{\varphi(x)}^r (\psi \circ f \circ \varphi^{-1}).$$

If ξ is a vector field on M, η is a vector field on N and ξ_t, η_t are the corresponding flows, then $(\xi_t, \eta_t)^r$ is a one-parameter family of diffeomorphisms of $J^r(M, N)$. This determines a vector field $(\xi, \eta)^r$ on $J^r(M, N)$ called the r -th prolongation of the pair (ξ, η) . In coordinates, if $\xi \equiv \xi^k(u) (\partial/\partial u^k)$ and $\eta \equiv \eta^s(v) (\partial/\partial v^s)$, then

$$(2) \quad (\xi, \eta)^t \equiv \xi^k \frac{\partial}{\partial u^k} + \eta^s \frac{\partial}{\partial v^s} + \left(\frac{\partial \eta^s}{\partial v^t} v_k^t - \frac{\partial \xi^k}{\partial u^t} v_t^s \right) \frac{\partial}{\partial v_k^s},$$

where $v_k^s = \partial v^s / \partial u^k$ are the additional coordinates on $J^1(M, N), k, l = 1, \dots, \dim M, s, t = 1, \dots, \dim N$. (In principle, the coordinate formula for $(\xi, \eta)^r$ can be deduced by iterating (2) and by the standard inclusions of the theory of non-holonomic jets.)

Consider further a fibered manifold $\pi : Y \rightarrow X$. Let ξ be a projectable vector field on Y , i.e. there is a unique vector field ξ_0 on X that is π -related with ξ . The space $J^r Y$ of all r -jets of the local sections of Y is a subset of $J^r(X, Y)$ invariant with

respect to $(\xi_0, \xi)^r$. The restriction $p^r \xi$ of $(\xi_0, \xi)^r$ to $J^r Y$ is the r -th prolongation of ξ in the sense of [2], [4]. Let

$$x^i, y^p; i, j, \dots = 1, \dots, n = \dim X, \quad p, q, \dots = 1, \dots, \dim Y - \dim X,$$

be local fiber coordinates on Y and $\xi \equiv \xi^i(x) (\partial/\partial x^i) + \xi^p(x, y) (\partial/\partial y^p)$. Specializing (2), we obtain

$$(3) \quad p^1 \xi \equiv \xi^i \frac{\partial}{\partial x^i} + \xi^p \frac{\partial}{\partial y^p} + \left(\frac{\partial \xi^p}{\partial x^i} + \frac{\partial \xi^p}{\partial y^q} y_i^q - \frac{\partial \xi^j}{\partial x^i} y_j^p \right) \frac{\partial}{\partial y_i^p},$$

where $y_i^p = \partial y^p / \partial x^i$, cf. [4].

2. Let G be a Lie groupoid over X with source projection a and target projection b . Denote by LG the vector bundle (over X) of all a -vertical tangent vectors on G at the units, i.e. every element of $(LG)_x, x \in X$, is of the form $j_0^1 \gamma(t)$, where $\gamma(t)$ is a curve on G satisfying $a \gamma(t) = x$ for all t and $\gamma(0) = e_x =$ the unit over x . Assume further that G acts on the left on a fibered manifold $\pi : Y \rightarrow X$ (in other words, Y is a fiber bundle associated with G), [9]. Every section $\varrho : X \rightarrow LG$ determines a vector field ϱ_Y on Y by

$$(4) \quad \varrho_Y(z) = j_0^1(\gamma(t) \cdot z),$$

$\pi(z) = x, \varrho(x) = j_0^1 \gamma(t)$, which will be called *the fundamental field* (or G -field) on Y determined by ϱ .

Example 1. Let $E \rightarrow X$ be a vector bundle and G the groupoid of all linear isomorphisms between the fibers of E . A G -field on E will be called a *linear vector field*. In linear fiber coordinates on E , the coordinate form of a linear vector field is

$$(5) \quad \xi^i(x) \frac{\partial}{\partial x^i} + \xi_q^p(x) y^q \frac{\partial}{\partial y^p}.$$

Example 2. Similarly one introduces the affine vector fields on affine bundles. In particular, it is well-known that $J^1 Y \rightarrow Y$ is an affine bundle for any fibered manifold Y .

Proposition 1. *The first prolongation $p^1 \xi$ of any projectable vector field ξ on Y is an affine vector field on $J^1 Y \rightarrow Y$.*

Proof is straightforward.

The target projection of G determines a fibered manifold $G_b := (b : G \rightarrow X)$ and G acts on G_b by the left multiplication. The fundamental field on G_b defined by a section $\varrho : X \rightarrow LG$ will be denoted by ϱ_G . Such a field is characterized by the property that it is both a -vertical and right-invariant (i.e. every $g \in G, ag = x, bg = y$ determines a mapping $a^{-1}(y) \rightarrow a^{-1}(x), g' \mapsto g' \cdot g$ and ϱ_G is invariant with

respect to all these mappings). If $\tau : X \rightarrow LG$ is another section, then the bracket $[\varrho_G, \tau_G]$ is also both a -vertical and right-invariant, so that there is a unique section $\{\varrho, \tau\} : X \rightarrow LG$ satisfying $\{\varrho, \tau\}_G = [\varrho_G, \tau_G]$. This endows LG with a Lie algebroid structure, [7].

Proposition 2. *If Y is a fiber bundle associated with G and ϱ, τ are two sections of LG , then the corresponding G -fields on Y satisfy*

$$(6) \quad [\varrho_Y, \tau_Y] = \{\varrho, \tau\}_Y.$$

Proof. The source projection defines another fibered manifold $G_a := (a : G \rightarrow X)$ and the action of G on Y is a mapping $\varkappa : G_a \oplus Y \rightarrow Y$, where \oplus means the fiber product over X . The zero vector field 0_Y of Y and ϱ_G determine a vector field $\varrho_G \oplus 0_Y$ on $G_a \oplus Y$. According to (4), $\varrho_G \oplus 0_Y$ is \varkappa -related with ϱ_Y , which proves Proposition 2.

Locally, G is isomorphic to $R^n \times H \times R^n$, where H is a Lie group and the multiplication is given by

$$(7) \quad (x_3, h_2, x_2) \cdot (x_2, h_1, x_1) = (x_3, h_2 h_1, x_1),$$

the product $h_2 h_1$ being defined in H . Further, Y is locally of the form $R^n \times F$, where F is a left H -space and the action of G on Y is given by

$$(8) \quad (x_2, h, x_1) \cdot (x_1, y) = (x_2, hy),$$

the latter product being determined by the action of H on F . Let

$$h^\alpha, \quad \alpha, \beta, \dots = 1, \dots, \dim H,$$

be local coordinates on H in a neighbourhood of the unit and let e_α be the induced basis of the Lie algebra of H . Then a section ϱ of LG can be locally written as

$$(9) \quad \varrho \equiv \varrho^i(x) \frac{\partial}{\partial x^i} + \varrho^\alpha(x) e_\alpha$$

and the coordinate formula for $\{\varrho, \tau\}$ is

$$(10) \quad \{\varrho, \tau\} \equiv \left(\varrho^j \frac{\partial \tau^i}{\partial x^j} - \tau^j \frac{\partial \varrho^i}{\partial x^j} \right) \frac{\partial}{\partial x^i} + \left(\varrho^i \frac{\partial \tau^\alpha}{\partial x^i} - \tau^i \frac{\partial \varrho^\alpha}{\partial x^i} + c_{\beta\gamma}^\alpha \varrho^\beta \tau^\gamma \right) e_\alpha,$$

provided $-c_{\beta\gamma}^\alpha$ are the structure constants of H , [8]. Further, let $A_\alpha^p(y) \partial/\partial y^p$ be the vector fields on F determined by e_α , [3]. Then we deduce by (8) the coordinate formula of ϱ_Y

$$(11) \quad \varrho_Y \equiv \varrho^i(x) \frac{\partial}{\partial x^i} + A_\alpha^p(y) \varrho^\alpha(x) \frac{\partial}{\partial y^p}.$$

By Proposition 2 and (11), we conclude that the mapping $\varrho \mapsto \varrho_Y$ is a Lie algebroid homomorphism of LG into the Lie algebroid of all projectable vector fields on Y .

3. Denote by $\Gamma(g, t)$ the flow of the vector field ϱ_G and set $\gamma(x, t) = \Gamma(e_x, t)$. Since Γ is also right-invariant, we have

$$(12) \quad \Gamma(g, t) = \gamma(bg, t) \cdot g,$$

i.e. Γ is determined by the values at the units of G .

The r -th prolongation G^r of G is a Lie groupoid over X defined as follows. The underlying set of G^r is the subset of all elements $A \in J^r G_a$ (= the r -th jet prolongation of fibered manifold $a : G \rightarrow X$) such that bA is an invertible r -jet of X into X , while the multiplication in G^r is given by

$$(13) \quad j_x^r g(u) \cdot j_y^r h(v) = j_y^r [g(b h(v)) \cdot h(v)],$$

provided $b h(y) = x$, [1]. As ϱ_G is a -vertical, it is a -related with the zero vector field of X and we can construct its r -th prolongation $p^r \varrho_G$ on $J^r G_a$. Obviously, G^r is an invariant subspace of $p^r \varrho_G$.

Proposition 3. *The restriction $p^r \varrho_G | G^r$ is a fundamental field on G^r , i.e. there exists a unique section $\varrho^r : X \rightarrow LG^r$ such that $\varrho_{G^r}^r = p^r \varrho_G | G^r$.*

Proof. According to (12), the flow Γ^r induced by Γ on G^r is given by

$$(14) \quad \Gamma^r(j_x^r g(u), t) = j_x^r [\gamma(b g(u), t) \cdot g(u)].$$

Multiplying on the right by $j_y^r h(v)$, we obtain

$$(15) \quad j_y^r [\gamma(bg(b h(v)), t) \cdot g(b h(v)) \cdot h(v)].$$

Using (13) we prove that Γ^r is a right-invariant flow, so that $p^r \varrho_G | G^r$ is a right-invariant vector field. Clearly, $p^r \varrho_G | G^r$ is also vertical with respect to the source projection of G^r , QED.

In the above construction, $\varrho^r(x)$ is fully determined by $j_x^r \varrho \in J^r(LG)$. This defines an identification $J^r(LG) \approx LG^r$; a detailed proof can be found in [6].

On the other hand, G^r acts on $J^r Y$ by

$$(16) \quad j_x^r g(u) \cdot j_x^r \sigma(u) = j_y^r [g((bg)^{-1}(v)) \cdot \sigma((bg)^{-1}(v))],$$

where $y = b g(x)$ and $(bg)^{-1}$ means the inverse map of a local diffeomorphism $u \mapsto b g(u)$ of X into itself, [1]. Hence ϱ^r induces a G^r -field $\varrho_{J^r Y}^r$ on $J^r Y$.

Proposition 4. *The latter field coincides with the r -th prolongation of ϱ_Y , i.e.*

$$(17) \quad p^r(\varrho_Y) = \varrho_{J^r Y}^r.$$

Proof consists in comparing (1), (4), (14), (16), QED.

For $r = 1$, we now deduce the coordinate expressions. Locally, we have $G_n^1 = \mathbb{R}^n \times H_n^1 \times \mathbb{R}^n$, [1], and the underlying manifold of H_n^1 is the product of $T_n^1 H$

(= the space of all n^1 -velocities on H) and $L_n^1 = GL(n, R)$. The induced coordinates $h^\alpha, h_i^\alpha = \partial h^\alpha / \partial x^i$ on $T_n^1 H$ and the canonical coordinates on L_n^1 determine a basis $e_\alpha, e_\alpha^i, e_j^i$ of the Lie algebra of H_n^1 . Using (3) and Proposition 3, we find the following coordinate expression of $q^1 : X \rightarrow LG^1$

$$(18) \quad q^1 \equiv q^i \frac{\partial}{\partial x^i} + q^\alpha e_\alpha + \frac{\partial q^\alpha}{\partial x^i} e_\alpha^i + \frac{\partial q^j}{\partial x^i} e_j^i.$$

On the other hand, $J^1 Y$ is locally of the form $R^n \times T_n^1 F$, [1]. According to [3], the vector fields on $T_n^1 F$ corresponding to $e_\alpha, e_\alpha^i, e_j^i$ are

$$A_\alpha^p \frac{\partial}{\partial y^p} + \frac{\partial A_\alpha^p}{\partial y^q} y_i^q \frac{\partial}{\partial y_i^p}, \quad A_\alpha^p \frac{\partial}{\partial y_i^p}, \quad -y_j^p \frac{\partial}{\partial y_i^p},$$

provided y_i^p are the additional coordinates on $T_n^1 F$. Hence the coordinate form of $q_{J^1 Y}^1$ is

$$(19) \quad q_{J^1 Y}^1 \equiv q^i \frac{\partial}{\partial x^i} + A_\alpha^p q^\alpha \frac{\partial}{\partial y^p} + \left(\frac{\partial A_\alpha^p}{\partial y^q} y_i^q q^\alpha + A_\alpha^p \frac{\partial q^\alpha}{\partial x^i} - y_j^p \frac{\partial q^j}{\partial x^i} \right) \frac{\partial}{\partial y_i^p}.$$

On the other hand, we also obtain this formula by applying (3) to (11), which yields another proof of Proposition 4.

4. First we introduce a general concept needed in Proposition 5. Let M be a manifold and $p_M : TM \rightarrow M$ the tangent bundle of M . There are two natural projections of TTM into TM , namely the bundle projection p_{TM} and the tangent map Tp_M . Consider further the canonical involution i of TTM . Let $A, B \in TTM$ satisfy $p_{TM}(A) = Tp_M(B)$ and $Tp_M(A) = p_{TM}(B)$. Then iB lies in $T_v TM$, $v = p_{TM}(A)$, and one verifies directly that the difference $A - iB$ belongs to the tangent space of the vector space $T_x M$, $x = p_M(v)$. Hence $A - iB$ is identified with an element of $T_x M$, which will be called the strong difference of A and B and denoted by $A \dot{-} B$. In coordinates, if $x^i, X^i = dx^i$ are local coordinates on TM and $A \equiv (x^i, X^i, dx^i, dX^i = a^i)$, $B \equiv (x^i, dx^i, X^i, dX^i = b^i)$, then

$$(20) \quad A \dot{-} B \equiv (x^i, a^i - b^i).$$

Consider now a projectable vector field ξ on $Y \rightarrow X$ over ξ_0 and a section σ of Y . Taking into account the corresponding flows φ_t and φ_{0t} , we construct a curve

$$(21) \quad t \mapsto \varphi_t^{-1}(\sigma(\varphi_{0t}(x)))$$

in the fiber Y_x , whose tangent vector $(L_\xi \sigma)(x) \in T_{\sigma(x)}(Y_x)$ will be called the Lie derivative of σ with respect to ξ at x . Evaluating (21), we find

$$(22) \quad L_\xi \sigma = \sigma_* \xi_0 - \xi_0 \sigma,$$

where $\sigma_*\xi_0$ is the image of ξ_0 by the differential of σ . In coordinates, if $\xi \equiv \xi^i(x) \cdot (\partial/\partial x^i) + \xi^p(x, y) (\partial/\partial y^p)$ and $\sigma \equiv \sigma^p(x)$, then

$$(23) \quad L_\xi \sigma \equiv \frac{\partial \sigma^p}{\partial x^i} \xi^i(x) - \xi^p(x, \sigma(x)).$$

In particular, if Y is a fiber bundle associated with a Lie groupoid G and ρ is a section of LG , then we write $L_\rho \sigma$ instead of $L_{\rho_Y} \sigma$. Geometrically, $(L_\rho \sigma)(x)$ is the tangent vector to the curve $\gamma^{-1}(x, t) \cdot \sigma(\gamma(x, t))$, where γ has the same meaning as in (12). In coordinates,

$$(24) \quad L_\rho \sigma \equiv \frac{\partial \sigma^p}{\partial x^i} \rho^i(x) - A_a^p(\sigma(x)) \rho^a(x).$$

Let $T(Y/X)$ be the bundle of all vertical tangent vectors on Y . This is a vector bundle over Y , but it can be also considered as a fibered manifold over X . Similarly to § 1, every projectable vector field ξ on Y is prolonged into a projectable vector field $\bar{\xi}$ on $T(Y/X) \rightarrow X$. Taking into account the inclusion $TY \subset J^1(R, Y)$, we deduce by (2) (with zero vector field on R) that

$$(25) \quad \bar{\xi} \equiv \xi^i \frac{\partial}{\partial x^i} + \xi^p \frac{\partial}{\partial y^p} + \frac{\partial \xi^p}{\partial y^q} Y^q \frac{\partial}{\partial Y^p},$$

provided $Y^p = dy^p$. Consider another projectable vector field η on Y . Since $L_\xi \sigma$ is a section of $T(Y/X) \rightarrow X$, we have defined the Lie derivative $L_{\bar{\eta}}(L_\xi \sigma)$. If we construct conversely $L_\xi(L_\eta \sigma)$, then the vectors $L_{\bar{\eta}}(L_\xi \sigma)(x)$, $L_\xi(L_\eta \sigma)(x) \in TT(Y_x)$ satisfy the conditions of the definition of the strong difference. By direct evaluation, we prove

Proposition 5. *It holds*

$$(26) \quad L_\xi(L_\eta \sigma) - L_{\bar{\eta}}(L_\xi \sigma) = L_{[\xi, \eta]} \sigma.$$

Given a vector bundle $E \rightarrow X$, every element $A \in T(E_x)$ is identified with a vector $tA \in E_x$. In particular, $tL_\xi \sigma$ is now a section of E as well. Moreover, if ξ and η are linear vector fields on E , then (5), (25) and (26) imply

$$(27) \quad tL_\xi(tL_\eta \sigma) - tL_{\bar{\eta}}(tL_\xi \sigma) = tL_{[\xi, \eta]} \sigma.$$

This formula generalizes a result by QUE, [8], and includes the classical case of the first order tensor bundles. However, we underline that (27) does not hold for general projectable vector fields on E .

5. The product $X \times X$ with the trivial partial composition $(x_3, x_2) \cdot (x_2, x_1) = (x_3, x_1)$ is a special Lie groupoid over X . The r -th prolongation of $X \times X$ is the groupoid $\Pi^r X$ of all invertible r -jets of X into X . The Lie algebroid $L(X \times X)$

coincides with TX . Hence every vector field ξ on X is prolonged into a section $\xi^r : X \rightarrow L(\Pi^r X)$. If $e_j^i, \dots, e_j^{i_1 \dots i_r}$ is the canonical basis of the r -th differential group L_r^n , and $\xi \equiv \xi^i(x) (\partial/\partial x^i)$, then we find by iterating (18)

$$(28) \quad \xi^r \equiv \xi^j \frac{\partial}{\partial x^j} + \frac{\partial \xi^j}{\partial x^i} e_j^i + \dots + \frac{\partial^r \xi^j}{\partial x^{i_1} \dots \partial x^{i_r}} e_j^{i_1 \dots i_r}.$$

Further, let Y be a fibered manifold associated with $\Pi^r X$ and σ a section of Y . Then $L_{\xi^r} \sigma =: L_{\xi} \sigma$ is called the Lie derivative of σ with respect to ξ . Moreover, if $A_j^{p^i}(y), \dots, A_j^{p^{i_1 \dots i_r}}(y)$ are the vector fields on the standard fiber F of Y corresponding to $e_j^i, \dots, e_j^{i_1 \dots i_r}$, then we obtain by (24) and (28)

$$(29) \quad L_{\xi} \sigma \equiv \frac{\partial \sigma^p}{\partial x^i} \xi^i - A_j^{p^i}(\sigma) \frac{\partial \xi^j}{\partial x^i} - \dots - A_j^{p^{i_1 \dots i_r}}(\sigma) \frac{\partial^r \xi^j}{\partial x^{i_1} \dots \partial x^{i_r}}.$$

This formula covers the classical cases of Lie differentiation.
