Spaces of continuous functions, 
Σ-products and Box Topology

J. ANGOA, Á. TAMARIZ-MASCARÚA

Abstract. For a Tychonoff space $X$, we will denote by $X_0$ the set of its isolated points and $X_1$ will be equal to $X \setminus X_0$. The symbol $C(X)$ denotes the space of real-valued continuous functions defined on $X$. $\Box \mathbb{R}^n$ is the Cartesian product $\mathbb{R}^n$ with its box topology, and $C(\Box \mathbb{R}^n)$ is $C(X)$ with the topology inherited from $\Box \mathbb{R}^X$. By $\hat{C}(X_1)$ we denote the set $\{f \in C(X_1) : f\text{ can be continuously extended to all of } X\}$. A space $X$ is almost-$\omega$-resolvable if it can be partitioned by a countable family of subsets in such a way that every non-empty open subset of $X$ has a non-empty intersection with the elements of an infinite subcollection of the given partition. We analyze $C(\Box X)$ when $X_0$ is $F_\sigma$ and prove: (1) for every topological space $X$, if $X_0$ is $F_\sigma$ in $X$, and $\emptyset \neq X_1 \subset \text{cl}_X X_0$, then $C(\Box X) \cong \Box \mathbb{R}^{X_0}$; (2) for every space $X$ such that $X_0$ is $F_\sigma$, $\text{cl}_X X_0 \cap X_1 \neq \emptyset$, and $X_1 \setminus \text{cl}_X X_0$ is almost-$\omega$-resolvable, then $C(\Box X)$ is homeomorphic to a free topological sum of $\leq |\hat{C}(X_1)|$ copies of $\Box \mathbb{R}^{X_0}$, and, in this case, $C(\Box X) \cong \Box \mathbb{R}^{X_0}$ if and only if $|\hat{C}(X_1)| \leq 2^{|X_0|}$. We conclude that for a space $X$ such that $X_0$ is $F_\sigma$, $C(\Box X)$ is never normal if $|X_0| > 80$ [La], and, assuming CH, $C(\Box X)$ is paracompact if $|X_0| = 80$ [Ru2]. We also analyze $C(\Box X)$ when $|X_1| = 1$ and when $X$ is countably compact, and we scrutinize under what conditions $\Box \mathbb{R}^n$ is homeomorphic to some of its “$\Sigma$-products”; in particular, we prove that $\Box \mathbb{R}^n$ is homeomorphic to each of its subspaces $\{f \in \Box \mathbb{R}^n : \{n \in \omega : f(n) = 0\} \subset p\}$ for every $p \in \omega^*$, and it is homeomorphic to $\{f \in \Box \mathbb{R}^n : \forall \epsilon > 0 \{n \in \omega : |f(n)| < \epsilon\} \in \mathcal{F}_0\}$ where $\mathcal{F}_0$ is the Fréchet filter on $\omega$.

Keywords: spaces of real-valued continuous functions, box topology, $\Sigma$-product, almost-$\omega$-resolvable space

Classification: 54C35, 54B10, 54D15

0. Introduction

All topological spaces considered in this article will be Tychonoff.

The spaces of continuous functions defined on a topological space $X$ and with values in $\mathbb{R}$, $C(X)$, have been widely studied as a purely algebraic structure ([GJ]), and with a topological-algebraic structure ([BNS], [DH]).

One of the natural topologies associated with $C(X)$ is the pointwise convergence topology, which is the topology in $C(X)$ inherited from the Tychonoff topology of $\mathbb{R}^X$. This space is usually denoted by $C_p(X)$. A classical general problem

on $C_p$-spaces consists of determining the relations between the topological properties of space $X$ with the topological properties of $C_p(X)$ ([Ar]).

A generalization of the Tychonoff topology for a product of topological spaces, is the box topology (see definition in Section 1) which was introduced by Tietze in [Ti]. The study of the box product of an infinite family of topological spaces has been a very useful source to construct some interesting topological spaces ([Ru1], [V]). With respect to paracompactness of box products, in 1963, in [Kn], the question, due to A.H. Stone, whether the cartesian product of an infinite collection of copies of the real line with its box topology is a normal space, was posed. In [Ru2], M.E. Rudin proved under CH that the box product of countably many $\sigma$-compact locally compact metrizable spaces is paracompact; and K. Kunen [Ku] showed, also using CH, that the box product of a countable family $\{K_n : n < \omega\}$ of compact spaces is paracompact if and only if the Lindelöf degree of $\Box_n < \omega K_n$ is equal to $\omega_1$. Moreover, E.K. van Douwen [vD] showed that a box product of a countable collection of metrizable separable spaces need not be normal. Finally, L.B. Lawrence [La] proved in ZFC that the product of an uncountable family of copies of the real line is not normal.

So, it seems natural to ask about the relations between the topological properties of a space $X$ and those of $C(X)$ with its box topology, which we denote by $C_\Box(X)$. In particular, it is natural to ask under what conditions on $X$, $C_\Box(X)$ is normal or paracompact (the set $C_\Box(X)$ being a closed subset of $\Box \mathbb{R}^X$). In [TV], A. Tamariz-Mascarúa and H. Villagás-Rodríguez analyzed the space $C_\Box(X)$ when $X$ is a topological space without isolated points. They obtained the following results (see the definition of an almost-$\omega$-resolvable space in Section 1):

**0.1 Theorem.** Let $X$ be a dense-in-itself space. Then,

1. $X$ is an almost-$\omega$-resolvable space iff $C_\Box(X)$ is a discrete space;
2. $\text{Con}(ZFC)$ implies $\text{Con}(ZFC^+)$ for every space $X$, $C_\Box(X)$ is a discrete subspace of $\Box \mathbb{R}^X$;
3. if $X$ is a Baire irresolvable space, then $C_\Box(X)$ is not a discrete space.

We recall here that a topological space $X$ is *irresolvable* if it is dense-in-itself and it is not the union of two disjoint dense subsets; and, of course, a space $X$ is *Baire irresolvable* if it is irresolvable and satisfies the Baire property. In [KST], it was proved that the existence of a Baire irresolvable space is equiconsistent with the existence of a measurable cardinal; then, the existence of a dense-in-itself space for which $C_\Box(X)$ is not discrete, is equiconsistent with the existence of a measurable cardinal (see [TV, Theorem 4.16]). In particular, if $X$ is a dense-in-itself almost-$\omega$-resolvable space, $C_\Box(X)$ is more than a paracompact space.

The purpose of this article is to analyze spaces $C_\Box(X)$ when the subset $X_0$ of isolated points of $X$ is empty, and to show the topological relations between $C_\Box(X)$ and $\Box \mathbb{R}^{X_0}$ and how the former can be expressed in terms of the latter. One of our main results states that for every space $X$ for which $Z = X \setminus \text{cl}_X X_0$ is
almost-$\omega$-resolvable and $X_0$ is an $F_\sigma$-subset of $X$, $C_\square(X)$ is a free topological sum of copies of $\square\mathbb{R}^{X_0}$. Concluding that, by the results of Rudin and Lawrence, if $X$ has the properties mentioned, $C_\square(X)$ is not normal if $|X_0| > \aleph_0$, and CH implies $C_\square(X)$ is paracompact when $|X_0| = \aleph_0$. We also obtain sufficient and necessary conditions on $X$ under which $C_\square(X)$ is homeomorphic to $\square\mathbb{R}^{X_0}$. One immediate conclusion which comes after these results is the fact that for spaces $X$ and $Y$ even with opposite topological properties, $C_\square(X) \not\cong C_\square(Y)$ can happen. This fact will allow us to decide when $\square\mathbb{R}^\kappa$ is or is not homeomorphic to some of its “$\Sigma$-products”. So, we can say that for a wide class of topological spaces $X$, $C_\square(X)$ is completely determined by some weak topological properties (of a set-theoretical type) of $X$ and $X_0$.

In Section 1 we give some basic definitions and preliminary results. In Section 2 we discuss spaces $C_\square(X)$ when $X_0$ is an $F_\sigma$-subset of $X$ and $\emptyset \neq X_1 = X \setminus X_0 \subset cl_X X_0$, and we prove that, in this case, $C_\square(X) \cong \square\mathbb{R}^{X_0}$. Section 3 is devoted to analyzing $C_\square(X)$ in a more general situation: $X_0$ is an $F_\sigma$-subset of $X$, $X^b = X_1 \cap cl_X X_0 \neq \emptyset$ and $Z = X \setminus cl_X X_0$ is an almost-$\omega$-resolvable space; we obtain that, in this case, $C_\square(X)$ is homeomorphic to a free topological sum of copies of $\square\mathbb{R}^{X_0}$.

In Sections 4 and 5 we study $C_\square(X)$ when $|X_1| = 1$ and when $X$ is countably compact, and we scrutinize under what conditions $\square\mathbb{R}^\kappa$ is homeomorphic to some of its “$\Sigma$-products”; in particular, we prove that $\square\mathbb{R}^\omega$ is homeomorphic to its subspaces $\Sigma_p^\square\mathbb{R}^\omega = \{ f \in \square\mathbb{R}^\omega : \{ n \in \omega : f(n) = 0 \} \in p \}$ for every $p \in \omega^\kappa$, and it is homeomorphic to $\Sigma^\square_{*\mathcal{F}_0}\mathbb{R}^\omega = \{ f \in \square\mathbb{R}^\omega : \forall \varepsilon > 0 \{ n \in \omega : |f(n)| < \varepsilon \} \in \mathcal{F}_0 \}$ where $\mathcal{F}_0$ is the Fréchet filter on $\omega$.

1. Basic definitions and preliminaries

For a set $X$ and a cardinal number $\kappa$, $\mathcal{P}(X)$ will be the collection of subsets of $X$, $|X|^\kappa$ is the collection of elements in $\mathcal{P}(X)$ having cardinality $\kappa$, and $|X|^{<\kappa}$ is the collection of elements in $\mathcal{P}(X)$ having cardinality $< \kappa$. For a function $f : X \to Y$ and a subset $B$ of $X$, $f \upharpoonright B$ is the restriction of $f$ to $B$. As we have already said, every topological space $X$ considered in this article will be completely regular and $T_2$; that is, Tychonoff. For a space $X$, $\beta X$ is the Stone-Cech compactification of $X$.

Let $\mathcal{F} = \{ X_\alpha : \alpha \in A \}$ be a collection of topological spaces. By $\square_{\alpha \in A} X_\alpha$, we will represent the Cartesian product $X = \prod_{\alpha \in A} X_\alpha$ of the family $\mathcal{F}$ endowed with the box topology. The box topology is that generated in $X$ by the open boxes; that is, by the subsets of the form $\prod_{\alpha \in A} O_\alpha$ where $O_\alpha$ is an open subset of $X_\alpha$ for each $\alpha \in A$. Recall that the Tychonoff topology in $X$ is generated by sets of the form $\prod_{\alpha \in A} O_\alpha$ where each $O_\alpha$ is open in $X_\alpha$ and the set $\{ \alpha \in A : O_\alpha \neq X_\alpha \}$ is finite. It is obvious that the Tychonoff topology in $X$ is contained in the box topology, and that they coincide iff $|A| < \aleph_0$.

It is well known that, for an infinite family $\{ X_\alpha : \alpha \in A \}$ of non-trivial topo-
logical spaces, $\square_{\alpha \in \mathcal{A}} X_\alpha$ is neither first countable nor locally compact, and it is never a topological vector space, but it is a topological group if each of the spaces $X_\alpha$ is a topological group, with group operation $+_{\alpha}$, when we consider the sum of two elements $(x_\alpha)_{\alpha \in \mathcal{A}}$ and $(b_\alpha)_{\alpha \in \mathcal{A}}$ in $\square_{\alpha \in \mathcal{A}} X_\alpha$ to be $(a_\alpha +_{\alpha} b_\alpha)_{\alpha \in \mathcal{A}}$. A good survey of the characteristics of the box topology can be found in [Wi].

For a topological space $X$ we denote by $\mathbb{R}^X$ the Cartesian product of $|X|$ copies of the real line $\mathbb{R}$ which can be considered as the set of functions from $X$ to $\mathbb{R}$. The subset of $\mathbb{R}^X$ whose elements are the continuous functions is denoted by $C(X)$. The space $\square \mathbb{R}^X$ (resp., $\mathbb{T} \mathbb{R}^X$) will be the set $\mathbb{R}^X$ with the box topology (resp., the Tychonoff topology), and $C(\square X)$ (resp., $C_\mathbb{T}(X)$) is the set $C(X)$ considered as a subspace of $\square \mathbb{R}^X$ (resp., $\mathbb{T} \mathbb{R}^X$).

A space $X$ is almost-$\omega$-resolvable if there is a partition $\{F_n : n < \omega\}$ of $X$ such that every non-empty open subset $V$ of $X$ has a non-empty intersection with each $F_n$ for every $n \in J$, where $J$ is an infinite subset of $\omega$. It will be useful to consider the empty space $\emptyset$ included in the class of almost-$\omega$-resolvable spaces.

For a space $X$, we will denote by $X_0$ the set of isolated points in $X$, and $X_1$ is its complement $X \setminus X_0$. The symbol $X^b$ represents the set $X_1 \cap \text{cl}_X X_0$ and $Z$ will denote the set $X \setminus (X^b \cup X_0)$.

Observe that, by Theorem 0.1, if $Z$ is an almost-$\omega$-resolvable space and $X^b$ is empty, then $C(\square X) = C(\square (Z \cup X_0)) \cong C(\square Z) \times C(\square X_0)$ is the free topological sum of $|C(X_1)|$ copies of the space $\square \mathbb{R}^\kappa$ where $\kappa = |X_0|$. So, in this case, we have already obtained a clear relation between $C(\square X)$ and $\square \mathbb{R}^X_0$. Hence, from now on we will assume that every space $X$ satisfies $X^b \neq \emptyset$.

The symbol $\hat{C}(X_1)$ stands for the set $\{f \in C(X_1) : f$ has a continuous extension to all of $X\}$. For each $\hat{x} \in \hat{C}(X_1)$, we take $A_\mathbb{R}(X) = \{f \in C(X) : f \mid X_1 = \hat{x}\}$. We will denote by $\hat{0}$ the function in $C(X_1)$ which is equal to 0 everywhere. For $f, g \in \mathbb{R}^X$, the function $f + g \in \mathbb{R}^X$ is defined as $(f + g)(x) = f(x) + g(x)$ for each $x \in X$. Every mention to an algebraic structure on $\mathbb{R}^X$ will refer to this operation. For two topological spaces $X$ and $Y$, we will write $X \cong Y$ if they are homeomorphic, and for topological groups $G$ and $H$, the symbol $H \cong G$ will signify that $H$ and $G$ are topologically isomorphic. Finally, for an element $x$ of a topological space $X$, $\mathcal{N}(x)$ will denote the system of neighborhoods of $x$ in $X$. It is easy to prove the following results.

1.1 Proposition. For a topological space $X$ we have:

1. $\square \mathbb{R}^X$ is a topological group;
2. $C(\square X)$ is a closed topological subgroup of $\square \mathbb{R}^X$;
3. $A_\mathbb{R}(X)$ is a closed topological subgroup of $C(\square X)$ for every $\hat{x} \in \hat{C}(X_1)$;
4. for $\hat{x} \in \hat{C}(X_1)$, $A_\mathbb{R}(X)$ and $A_\mathbb{R}(X)$ are topologically isomorphic;
5. the family $\{A_\mathbb{R}(X) : \hat{x} \in \hat{C}(X_1)\}$ is a partition of $C(X)$.

(The referee pointed out to the authors that Erik van Douwen was probably
the first to observe, in 1975, that the box product of topological groups is a
topological group.)

For a subset $Y$ of $X$, the symbol $\pi_Y$ will represent the natural projection from
$\Box \mathbb{R}^X$ to $\Box \mathbb{R}^Y$; that is, $\pi_Y$ is the function defined by $\pi_Y(f) = f \upharpoonright Y$. If $Y$ is
the one-point set $\{y\}$, we will write $\pi_y$ instead of $\pi_{\{y\}}$. The following lemma is very
useful.

1.2 Lemma. Let $X$ be a topological space and let $Y$ be a subset of $X$ containing $X_0$. Then, the function $\phi = \pi_Y \upharpoonright A_0(X) : A_0(X) \to \Box \mathbb{R}^Y$ is an isomorphic
embedding.

Proof: It is trivial that $\phi$ is one-to-one and furthermore $\phi(f - g) = (f - g) \upharpoonright Y = (f \upharpoonright Y) - (g \upharpoonright Y) = \phi(f) - \phi(g)$. Besides, if for each $x \in Y$ we take an
open subset $G_x$ of $\mathbb{R}$ which has 0 as one of its elements, then $\phi^{-1}[\prod_{x \in Y} G_x] = A_0(X) \cap \prod_{x \in Y} H_x$ where $H_x = G_x$ if $x \in Y$ and $H_x = \mathbb{R}$ if $x \notin Y$. So, $\phi$ is
a continuous function. Finally, if for each $x \in X$, $H_x$ is an open subset of $\mathbb{R}$
containing 0, then $\phi[\prod_{x \in X} H_x \cap A_0(X)] = \prod_{x \in Y} H_x \cap \phi[A_0(X)]$. □

Let $Y$ be a set, $S \subset Y$, $T = Y \setminus S$ and let $\mathcal{F} = \{F_n : n < \omega\}$ be a partition of $S$
(that is, $\bigcup_{n < \omega} F_n = S$, $F_n \neq \emptyset$ for each $n < \omega$, and if $n \neq m$, then $F_n \cap F_m = \emptyset$).
We define $E(\mathcal{F}) \subset \Box \mathbb{R}^Y$ as $E(\mathcal{F}) = \bigcap_{k < \omega} E_k(\mathcal{F})$, and $E_k(\mathcal{F}) = \bigcup_{m < \omega} E_{k,m}(\mathcal{F})$,
where

$$E_{k,m}(\mathcal{F})(x) = \begin{cases} \mathbb{R} & \text{if } x \in F_i \text{ and } i \leq m, \\ \left[-\frac{1}{2^{1+k}}, \frac{1}{2^{1+k}}\right] & \text{if } x \in F_i \text{ and } m < i, \\ \mathbb{R} & \text{if } x \in T. \end{cases}$$

Let us obtain some properties of the sets just defined (see [Ru3]).

1.3 Proposition. Let $Y$ be a topological space and let $\mathcal{F}$ be a partition of $S \subset Y$. Then, $E(\mathcal{F})$ is a dense topological subgroup of $\Box \mathbb{R}^Y$.

Proof: Let $\mathcal{F} = \{F_n : n < \omega\}$ be a partition of $S$. If $z \in E(\mathcal{F})$, there is a strictly
increasing sequence $\{m_k : k < \omega\}$ such that $z \in E_{k,m_k}(\mathcal{F})$ for each $k < \omega$. We
define the following open box $W$ which contains $z$:

$$W(x) = \begin{cases} \mathbb{R} & \text{if } x \in F_i, i \leq m_1, \\ \left(-\frac{1}{2^{1+k-1}}, \frac{1}{2^{1+k-1}}\right] & \text{if } x \in F_i, m_k < i \leq m_{k+1} \text{ and } k \geq 1, \\ \mathbb{R} & \text{if } x \notin S. \end{cases}$$

Let $h \in W$. We take $t_{k-1} = m_k$ for $k \geq 1$. Trivially, the sequence $\{t_{k-1} : 1 \leq k < \omega\}$ is strictly increasing and $h \in E_{k-1,t_{k-1}}(\mathcal{F})$ for all $k \geq 1$. Thus, $W \subset E(\mathcal{F})$; that is, $E(\mathcal{F})$ is open.

Now, let $w \notin E(\mathcal{F})$. There exists $k_0 < \omega$ such that for every $m$ there are
$i_m > m$ and $x_{i_m} \in F_{i_m}$ such that $w(x_{i_m}) \notin \left(-\frac{1}{2^{1+m+k_0}}, \frac{1}{2^{1+m+k_0}}\right]$. We take $A \subset \omega$
for which \( \{ i_m : m \in A \} = \{ i_m : m < \omega \} \) and for all \( n, m \in A \) with \( n \neq m, i_m \neq i_n \). For each \( m \in A \), let \( V_{i_m} \) be an open subset of \( \mathbb{R} \) such that \( w(x_{i_m}) \in V_{i_m} \) and \( V_{i_m} \cap [-\frac{1}{2^{m+\kappa_0}}, \frac{1}{2^{m+\kappa_0}}] = \emptyset \). Take \( O \) as the open box defined by \( O(x_{i_m}) = V_{i_m} \) for each \( m \in A \), and \( O(x) = \mathbb{R} \) if \( x \notin \{ x_{i_m} : m \in A \} \). It happens that \( w \in O \) and \( O \subset \square \mathbb{R}^Y \setminus E(\mathcal{F}) \); so, \( E(\mathcal{F}) \) is closed.

Now, let \( f, g \in E(\mathcal{F}) \). Take two sequences \( \{m_k : k < \omega \} \) and \( \{l_k : k < \omega \} \) satisfying: for all \( k < \omega \) and for all \( i > m_k \), if \( x \in F_i \) then \( f(x) \in \left[ -\frac{1}{2^{i+k}}, \frac{1}{2^{i+k}} \right] \), and for all \( j > l_k \), if \( y \in F_j \) then \( g(y) \in \left[ -\frac{1}{2^{j+k}}, \frac{1}{2^{j+k}} \right] \). We take \( t_{k-1} = \max\{m_k, l_k\} \) for \( k \geq 1 \). We have that \( f - g \in E_{k-1, t_{k-1}}(\mathcal{F}) \) for all \( k \geq 1 \). Therefore, \( f - g \in E(\mathcal{F}) \) and, since \( \emptyset \in E(\mathcal{F}) \), we conclude that \( E(\mathcal{F}) \) is a topological subgroup of \( \square \mathbb{R}^Y \).

We need to introduce the following definition which relativizes the concept of almost-\( \omega \)-resolvability.

1.4 Definition. Let \( X \) be a topological space, and let \( A \) and \( B \) be subsets of \( X \).
We say that \( A \) is almost-\( \omega \)-resolvable with respect to \( B \) (briefly: \( A \) is a-\( \omega \)-rwt\( B \)), if there is a partition \( \{ F_n : n < \omega \} \) of \( A \), such that for every open subset \( O \) of \( X \) which has a non-empty intersection with \( B \), \( |\{ n : F_n \cap O \neq \emptyset \}| = \aleph_0 \). Such a partition is called a resolution of \( A \) with respect to \( B \).

In the following proposition we emphasize the relation between the concepts just defined and the structure of \( C(\square X) \). Recall that \( A_{\widehat{x}}(X) \) is closed in \( C(\square X) \) for all \( \widehat{x} \in \hat{C}(X_1) \). First, a technical result.

1.5 Lemma. Let \( S \) and \( T \) be two subsets of a topological space \( Y \). If \( S \) is a-\( \omega \)-rwt\( T \), \( \{ F_n : n < \omega \} \) is a resolution of \( S \) with respect to \( T \), \( g \in C(Y) \) and \( O_g \) is the open box constituted by those elements \( f \) in \( C(Y) \) such that \( f(x) \in (g(x) - \frac{1}{2^{i+k}}, g(x) + \frac{1}{2^{i+k}}) \) if \( x \in F_n \), then \( g \upharpoonright T = h \upharpoonright T \) holds for every \( h \in O_g \).

Proof: Assume that there are \( h \in O_g \) and \( z \in T \) such that \( 0 < |h(z) - g(z)| = \epsilon \). Since \( g \) and \( h \) are continuous, we can take an element \( V \) in \( N(z) \), the system of neighborhoods of \( z \), such that \( g(V) \subset (g(z) - \frac{1}{2}, g(z) + \frac{1}{2}) \) and \( h(V) \subset (h(z) - \frac{1}{2}, h(z) + \frac{1}{2}) \). There is \( x \in S \) such that \( x \in F_n \cap V \) for an \( n \in \omega \) such that \( \frac{1}{2^{i+k}} < \frac{1}{2^{i+k}} \). For this \( x \), \( |h(x) - g(x)| < \frac{1}{2} \), \( |h(z) - h(x)| < \frac{1}{2} \) and \( |g(x) - g(z)| < \frac{1}{2} \); so, \( |h(z) - g(z)| < \epsilon \), a contradiction. Then, \( h(z) = g(z) \) for every \( z \in T \). \( \square \)

1.6 Proposition. A space \( X \) is a-\( \omega \)-rwt\( X_1 \) if and only if \( A_{\emptyset}(X) \) is an open subset of \( C(\square X) \).

Proof: That \( A_{\emptyset}(X) \) is open in \( C(\square X) \) is a consequence of Lemma 1.5; we just have to take \( X = S \) and \( X_1 = T \).

Now, let us assume that \( A_{\emptyset}(X) \) is an open subset of \( C(\square X) \). Since the function \( \emptyset \), which is equal to 0 everywhere, belongs to \( A_{\emptyset}(X) \), for each \( x \in X \) there
exists an open subset $G_x$ of $\mathbb{R}$ such that $
exists \in (\prod_{x \in X} G_x) \cap C(X) \subset A_0(X)$. We define $d(x) = \min\{n < \omega : \left(-\frac{1}{2^n}, \frac{1}{2^n}\right) \subset G_x\}$ and $F_n = \{x \in X : d(x) = n\}$. It is clear that $\{F_n : n < \omega\}$ is a partition of $X$.

We will prove that $\{F_n : n < \omega\}$ is a resolution for $X$ with respect to $X_1$. Assume the contrary; that is, there are $z \in X_1$, an open $V \in \mathcal{N}(z)$ and $n_0 < \omega$ satisfying $V \cap F_{n_0} = \emptyset$ for every $n > n_0$. Let $H : X \rightarrow \left[0, \frac{1}{2^{n_0}}\right]$ be a continuous function for which $H(X \setminus V) \subset \{0\}$ and $H(z) = \frac{1}{2^{n_0}}$. If $x \in V$, then $d(x) \leq n_0$. So for every $x \in V$, we have $\frac{1}{2^{n_0}} < \frac{1}{2^{d(x)}}$, and $H(x) \leq \frac{1}{2^{n_0}}$. Thus, for every $x \in V$, $H(x) \in \left(-\frac{1}{2^{d(x)}}, \frac{1}{2^{d(x)}}\right) \subset G_x$. On the other hand, if $x \in X \setminus V$, $H(x) = 0 \in G_x$. So $H \in (\prod_{x \in X} G_x) \cap C(X) \subset A_0(X)$. Hence, $H(z) = 0$ which is a contradiction. We conclude that $\{F_n : n < \omega\}$ is a resolution of $X$ with respect to $X_1$. \hfill \Box

As a consequence of Propositions 1.1 and 1.6, we obtain:

1.7 Corollary. Let $X$ be a-$\omega$-rwrt$X_1$. Then,

(1) for each $\hat{x} \in C(X_1)$, $A_{\hat{x}}(X)$ is a clopen subset of $C(\Box(X))$, and

(2) $C(\Box(X)) = \bigoplus_{\hat{x} \in C(X_1)} A_{\hat{x}}(X) \cong \bigoplus_{\hat{x} \in C(X_1)} (A_0(X))_{\hat{x}}$ where each $(A_0(X))_{\hat{x}}$

is a copy of $A_0(X)$.

If $X_0$ is a-$\omega$-rwrt$X_1$, then $X$ is a-$\omega$-rwrt$X_1$, and there exists a space $X$ which

is a-$\omega$-rwrt$X_1$ and $X_0$ is not a-$\omega$-rwrt$X_1$ (see an example in the paragraph before

Problem 2.8). From now on, under a complete minimal system of representatives of the cosets belonging to a quotient space $X/\sim$ we will understand a subset $J$ of $X$ such that $X/\sim = \bigcup_{x \in J} [x]$ and $[x] \neq [y]$ for each pair $x, y$ of different elements in $J$, where $[x]$ is the class of equivalence of $x$ related to the equivalence relation $\sim$. It is not difficult to prove the following result.

1.8 Proposition. If $X_1$ is almost-$\omega$-resolvable, then $X$ is a-$\omega$-rwrt$X_1$.

1.9 Remark. For a partition $\mathcal{F}$ of the set $X_0$ of isolated points of a space $X$,

we can consider the clopen topological subgroup $E(\mathcal{F})$ of $\Box(X)$, as was defined before Proposition 1.3. For each $f, g \in A_0(X)$, $(E(\mathcal{F}) \cap A_0(X)) + f$ and

$(E(\mathcal{F}) \cap A_0(X)) + g$ are clopen topologically isomorphic subgroups of $A_0(X)$. So,

for a complete minimal system $D_1$ of representatives of the cosets belonging to

the quotient group $A_0(X)/[E(\mathcal{F}) \cap A_0(X)]$, we have

$$A_0(X) = \bigoplus_{f \in D_1} \left(E(\mathcal{F}) \cap A_0(X)\right) + f.$$ 

So, we obtain:

1.10 Proposition. If $X$ is a-$\omega$-rwrt$X_1$, $\mathcal{F}$ is a resolution of $X$ with respect to

$X_1$ and $D_1$ is a complete minimal system of representatives of the cosets belonging
to the quotient $A_0^2(X)/[E(\mathcal{F}) \cap A_0^2(X)]$, then

$$C_\square(X) \simeq \bigoplus_{\bar{x} \in \tilde{C}(X_1). f \in D_1} \left[ E(\mathcal{F}) \cap A_0^2(X) \right]_{\bar{x}, f},$$

where each $(E(\mathcal{F}) \cap A_0^2)_{\bar{x}, f}$ is a copy of $E(\mathcal{F}) \cap A_0^2$.

Now we are going to give some results about box products and their $\sigma$-products which will be useful for our purposes. The important role which the $\sigma$-products play in the general study of box products was emphasized in [NyP].

As usual, for a topological space $X$, $l(X)$, $d(X)$, $c(X)$ and $e(X)$ denote the Lindelöf number, density, cellularity and extent of $X$, respectively (see [H] for definitions).

For a family $\{X_\alpha : \alpha \in A\}$ of topological spaces and $x \in \prod_{\alpha \in A} X_\alpha = X$, let $\sigma_x$ be the $\sigma$-product of $X$; that is, $\sigma_x = \{y \in X : |\{\alpha \in A : y(\alpha) \neq x(\alpha)\}| < \aleph_0\}$. We denote by $\sigma_x^2(\prod_{\alpha \in A} X_\alpha)$ (or simply, $\sigma_x^2$) the set $\sigma_x$ with the topology inherited from $\square_{\alpha \in A} X_\alpha$.

The following result is due to M.E. Rudin ([Ru3, p. 55]).

1.11 Proposition. Let $\kappa$ be an infinite cardinal number, and let $\{X_\alpha : \alpha < \kappa\}$ be a family of connected Tychonoff spaces. If $x \in \square_{\alpha < \kappa} X_\alpha$ and $C_x$ is the connected component of $x$ in $\square_{\alpha < \kappa} X_\alpha$, then $C_x = \sigma_x$.

1.12 Proposition. For each infinite cardinal number $\kappa$ and every $x \in \square \mathbb{R}^\kappa$,

$$l(\sigma_x^\square \mathbb{R}^\kappa) = e(\sigma_x^\square \mathbb{R}^\kappa) = d(\sigma_x^\square \mathbb{R}^\kappa) = c(\sigma_x^\square \mathbb{R}^\kappa) = \kappa.$$

Proof: For each $J \in [\kappa]^{< \aleph_0} = \{A \subset \kappa : |A| < \aleph_0\}$, let $H_J \subset \square \mathbb{R}^\kappa$ be the box defined by $H_J(\alpha) = \mathbb{R}$ if $\alpha \in J$ and $H_J(\alpha) = \{x(\alpha)\}$ if $\alpha \notin J$. The set $H_J$ with the box topology is homeomorphic to $T \mathbb{R}^J$, which is a Lindelöf space. Thus, for each open cover $\mathcal{C}$ of $\sigma_x^\square \mathbb{R}^\kappa$, and for each $J \in [\kappa]^{< \aleph_0}$, we can select a countable subfamily $\mathcal{C}_J$ of $\mathcal{C}$ such that $H_J \subset \bigcup \mathcal{C}_J$. Since $\sigma_x^\square \mathbb{R}^\kappa = \bigcup_{J \in [\kappa]^{< \aleph_0}} H_J$, $D = \bigcup_{J \in [\kappa]^{< \aleph_0}} \mathcal{C}_J$ is a subcollection of $\mathcal{C}$ which covers $\sigma_x^\square \mathbb{R}^\kappa$ and has cardinality $\leq \kappa$. So, $l(\sigma_x^\square \mathbb{R}^\kappa) \leq \kappa$.

Now, for each $x < \kappa$, we take $z_\delta \in \mathbb{R} \setminus \{x(\delta)\}$. We define for each $\alpha < \kappa$ $t_\alpha(\delta) = \begin{cases} z_\delta & \text{if } \alpha = \delta, \\ x(\delta) & \text{if } \alpha \neq \delta. \end{cases}$ The subset $D = \{t_\alpha : \alpha < \kappa\}$ of $\sigma_x^\square \mathbb{R}^\kappa$ is closed and discrete. We conclude that $\kappa \leq e(\sigma_x^\square \mathbb{R}^\kappa) \leq l(\sigma_x^\square \mathbb{R}^\kappa) \leq \kappa$.

Now, we are going to make some calculations in order to obtain the density of $\sigma_x^\square \mathbb{R}^\kappa$. For each $J \in [\kappa]^{< \aleph_0}$, we have that $d(T \mathbb{R}^J) = \aleph_0$. So, for each
$J \in [\kappa]^{<\aleph_0}$, there exists $D_J \subset H_J$ which is countable and dense in $H_J$. Thus, the set $D = \bigcup_{J \in [\kappa]^{<\aleph_0}} D_J$ is dense in $\sigma_x^\mathbb{R}^\kappa$. Since $|D| \leq \kappa$, $d(\sigma_x^\mathbb{R}^\kappa) \leq \kappa$.

Let $A$ be a subset of $\sigma_x^\mathbb{R}^\kappa$ with cardinality $< \kappa$. For each $a \in A$, let $J_a \in [\kappa]^{<\aleph_0}$ be such that $a \in H_{J_a}$. We take $T = \bigcup_{a \in A} J_a$. We have that $|T| \leq |A| < \kappa$. Let $\alpha_0$ be an element of $\kappa \setminus T$ and $O = \prod_{\alpha < \kappa} O_\alpha$ where $O_\alpha = \mathbb{R}$ if $\alpha \neq \alpha_0$, and $O_{\alpha_0}$ is an open subset of $\mathbb{R}$ which does not contain $x(\alpha_0)$. It is clear that $A \cap O = \emptyset$; then $A$ cannot be dense in $\sigma_x^\mathbb{R}^\kappa$. So, we can conclude that $d(\sigma_x^\mathbb{R}^\kappa) = \kappa$. \qed

1.13 Corollary. Let $\kappa$ and $\tau$ be infinite cardinal numbers. Then, $\square^\mathbb{R}^\kappa \simeq \square^\mathbb{R}^\tau$ if and only if $\square^\mathbb{R}^\kappa \cong \square^\mathbb{R}^\tau$, if and only if $\kappa = \tau$.

Proof: Let $\psi : \square^\mathbb{R}^\kappa \rightarrow \square^\mathbb{R}^\tau$ be a homeomorphism, and let $x \in \square^\mathbb{R}^\kappa$. By Proposition 1.11, we must have $\sigma_x^\mathbb{R}^\kappa \cong \sigma_{\psi(x)}^\mathbb{R}^\tau$. Now, Proposition 1.12 produces $\kappa = \tau$. \qed

We will prove something more general than this corollary in Section 3 (see Corollary 3.4).

In order to describe $C_\square(X)$, it will be convenient to keep in mind some results concerning the cardinality of $C(X)$. The following result was proved by W.W. Comfort and A.W. Hager in [CH].

1.14 Proposition. For a space $X$, $|C(X)| = w(\beta X)^\omega$.

2. Spaces $C_\square(X)$ when $X_0$ is an $F_\sigma$-set and $Z = \emptyset$

Recall that for a space $X$ we are denoting by $X_0$ its subset of isolated points, and $X_1$ is equal to $X \setminus X_0$. In this section we will analyze spaces $C_\square(X)$ when $X_0$ is an $F_\sigma$-subset of $X$ and $\emptyset \neq X_1 \subset cl_{X} X_0$. Some examples of spaces having these characteristics are: the convergent sequence $\{0\} \cup \{1/n : n \in \mathbb{N}\} \subset \mathbb{R}$, the Stone-Čech compactification $\beta \omega$ of the natural numbers, every Mrówka-Isbell space (or $\Psi$-space, see [GJ]) $\Psi(A)$, and the countable Fréchet-Urysohn fan $V(\aleph_0)$ ([Ar]). The main result of this section (Theorem 2.4) proclaims that for every space $X$ satisfying these properties, its related space of real-valued continuous functions $C_\square(X)$ is a box product of real lines.

Let $\mathcal{F} = \{F_n : n < \omega\}$ be a partition of $X_0$. We denote simply by $E(\mathcal{F})$ the subset of $\square^\mathbb{R}^X$ as was constructed before Proposition 1.3, when $Y = X$ and $S = X_0$; and we denote by $E_0(\mathcal{F})$ the subset of $\square^\mathbb{R}^{X_0}$ obtained in a similar way but when $Y = S = X_0$.

The following lemma describes the relation between $E(\mathcal{F})$ and $E_0(\mathcal{F})$ for a partition $\mathcal{F}$ of $X_0$.

2.1 Lemma. Let $\mathcal{F} = \{F_n : n < \omega\}$ be a partition of $X_0$, where each $F_n$ is a closed subset of $X$. Then, $\phi' = \pi_{X_0} \upharpoonright (E(\mathcal{F}) \cap A_0^{-}(X)) : E(\mathcal{F}) \cap A_0^{-}(X) \rightarrow E_0(\mathcal{F})$ is a topological isomorphism.
Proof: Because of Lemma 1.2 and the fact that $E(\mathcal{F})$ is open, we conclude that $\phi'$ is an embedding, and obviously $\phi'[E(\mathcal{F}) \cap A_0(X)] \subset E_0(\mathcal{F})$. The only part of the proof not entirely trivial refers to the surjection of $\phi'$. Let $h \in E_0(\mathcal{F})$, and let $h' \in \mathbb{R}^X$ with $h' \mid X_0 = h$ and $h'(z) = 0$ for every $z \in X_1$; then, $h' \in A_0(X)$. In fact, let $z \in X_1$ and $\epsilon > 0$, and let $\{m_k < \omega : k < \omega \}$ be a strictly increasing sequence of natural numbers such that $h \in E_0^{k,m_k}$ for all $k < \omega$. Let us take $k > 0$ such that $\frac{1}{2^m} < \epsilon$. The set $X \setminus (\bigcup_{i \leq m} F_i)$ is a neighborhood of $z$, $h'((X \setminus (\bigcup_{i \leq m} F_i)) \subset (-\epsilon, \epsilon)$ and $h'(z) = 0 \in (-\epsilon, \epsilon)$. We conclude that $h' \in A_0(X)$. It is clear that $h' \in E(\mathcal{F})$ and $\phi'(h') = h$. \hfill \Box

We define a relation of equivalence $\sim$ on $\mathbb{R}^X$: for $f, g \in \mathbb{R}^X$, $f \sim g$ if and only if for each $\epsilon > 0$ and each $z \in X_1$, there exists $V \in \mathcal{N}(z)$ such that $(f - g)(V \cap X_0) \subset (-\epsilon, \epsilon)$. For each $f \in \mathbb{R}^X$, $[f]$ is the $\sim$-class of equivalence of $f$.

2.2 Lemma. The relation $\sim$ is a relation of equivalence, and for $f, g \in \mathbb{R}^X$, if $f - g \in E_0(\mathcal{F})$, then $f \sim g$.

Proof: It is easy to confirm that $\sim$ is of equivalence. Now, assume that there are $z_0 \in X_1$ and $\epsilon_0 > 0$ such that for each $V \in \mathcal{N}(z_0)$, there is $x_V \in V \cap X_0$ such that $(f - g)(x_V) \notin (-\epsilon_0, \epsilon_0)$. Let $k < \omega$ be such that $\frac{1}{2^m} < \epsilon_0$. Fix a $m < \omega$. It is clear that $V_1 = (X \setminus \bigcup_{i \leq m} F_i) \in \mathcal{N}(z_0)$. Let $x_{V_1} \in V_1 \cap X_0$ satisfying $(f - g)(x_{V_1}) \notin (-\epsilon_0, \epsilon_0)$. In particular, there exist $i_m > m$, such that $x_{V_1} \in F_{i_m}$. Hence, $(f - g)(x_{V_1}) \notin \left[ -\frac{1}{2^{i_m + 1}}, \frac{1}{2^{i_m + 1}} \right]$; that is, $f - g \notin E_0(\mathcal{F})$. \hfill \Box

In order to prove the main result of this section (Theorem 2.4) we are next going to prove a proposition which is apparently less general.

2.3 Proposition. Assume that a space $X$ satisfies:

1. $\emptyset \neq X_1 \subset cl_X X_0$,
2. there is a partition $\{F_n : n < \omega\}$ of $X_0$ constituted by closed subsets of $X$, and
3. there is a partition $\{C_\alpha : \alpha < |X_0|\}$ of $X_0$ such that
   a) $|C_\alpha \cap F_n| \leq 1$ for each $\alpha < |X_0|$ and each $n < \omega$, and
   b) $J_\alpha = \{n < \omega : C_\alpha \cap F_n \neq \emptyset\}$ is infinite for each $\alpha < |X_0|$.

Then, $A_0(X) \cong \Box_\mathbb{R}^{X_0} \cong C(\Box)(X)$.

Proof: Let $\mathcal{F} = \{F_n : n < \omega\}$ be a partition of $X_0$ which testifies (2) and (3) in this proposition. Let $D_0 \subset \mathbb{R}^{X_0}$ be a minimal complete system of representatives of the cosets in $\Box \mathbb{R}^{X_0} / E_0(\mathcal{F})$, and let $D_1 \subset A_0(X)$ be a complete minimal system of representatives of $A_0(X) / [A_0(X) \cap E(\mathcal{F})]$. By Proposition 1.3, Remark 1.9 and Lemma 2.1, we have that (a) $\Box \mathbb{R}^{X_0} = \bigoplus_{f \in D_0} (E_0(\mathcal{F}) + f)$ and (b) $C(\Box)(X) \cong \bigoplus_{\bar{x} \in \mathcal{C}(X_1), f \in D_1} ([A_0(X) \cap E(\mathcal{F})] + f)_{\bar{x}}$, where each term that appears in the
sum in (a) is topologically isomorphic to each term that appears in the sum in (b).

Because of the definitions of $E_0(\mathcal{F})$ and $E(\mathcal{F})$, we have that for $f, g \in A_0(X)$, $f - g \in E(\mathcal{F})$ if and only if $(f \mid X_0) - (g \mid X_0) \in E_0(\mathcal{F})$. For this reason $|D_1| \leq |D_0|$.

We are going to prove now that $|\widehat{C}(X_1)| \leq |D_0|$. Let $\mathbb{R}^{X_0}/\sim$ be the quotient set determined by the relation $\sim$ defined before Lemma 2.2. The relation $H : \widehat{C}(X_1) \to \mathbb{R}^{X_0}/\sim$ which sends each $\widehat{x}$ to $[f_x]_0$ (where $f_x$ is an element of $A_\varnothing(X)$) is a well defined injective function. So, $|\widehat{C}(X_1)| \leq |\mathbb{R}^{X_0}/\sim|$. Now, using Lemma 2.2 we obtain $|\widehat{C}(X_1)| \leq |D_0|$.

Hence, we have already proved that $|\widehat{C}(X_1)| \cdot |D_1| \leq |D_0|$. Now we are going to prove that in fact $|\widehat{C}(X_1)| \cdot |D_1|$ is equal to $|D_0|$.

Recall that we are assuming that $X$ has properties (1), (2) and (3) listed in our proposition. For each $\alpha < |X_0|$, we can enumerate $C_{\alpha}$ as $\{x_{\alpha,n} : n \in J_{\alpha}\}$ in such a way that for every $n \in J_{\alpha}$, $x_{\alpha,n} \in F_n$. So, for each $A \in \mathcal{P}(|X_0|)$, we define $f_A \in \mathbb{R}^X$ as:

$$f_A(y) = \begin{cases} \frac{1}{2^n} & \text{if } y = x_{\alpha,n}, \alpha \in A \text{ and } n \in J_{\alpha}, \\ 0 & \text{otherwise.} \end{cases}$$

Observe that $f_A \in A_0(X)$. Moreover, for every two different subsets $A, B \in \mathcal{P}(|X_0|)$, $f_A - f_B \notin E(\mathcal{F})$ because of condition (3). Therefore, the function $T : \mathcal{P}(|X_0|) \to A_0(X)/A_0(X) \cap E(\mathcal{F})$

where $T(A) = A_0(X) \cap E(\mathcal{F}) + f_A$, is injective. We conclude that $2^{|X_0|} \leq |D_1|$.

Since $|D_0| \leq 2^{|X_0|}$, $|D_0| = |\widehat{C}(X_1)| \cdot |D_1|$.

Therefore, $A_0(X) \cong \square \mathbb{R}^{X_0} \cong C\Box(X)$. \hfill \Box

Next, the main result of this section.

**2.4 Theorem.** Let $X$ be a space such that $X_0$ is an $F_\sigma$-subset of $X$ and $\emptyset \neq X_1 \subset \text{cl}_X X_0$. Then,

$$A_0(X) \cong C\Box(X) \cong \square \mathbb{R}^{X_0}.$$ 

**Proof:** In order to prove this theorem we only have to construct two partitions $\mathcal{F} = \{F_n : n < \omega\}$ and $\mathcal{C} = \{C_\alpha : \alpha < |X_0|\}$ of $X_0$ satisfying (2) and (3) in Proposition 2.3.

Since $X_0$ is an $F_\sigma$-subset of $X$, there is a disjoint family $\mathcal{E} = \{E_i : i < \omega\}$ of closed subsets of $X$ covering $X_0$.

**First case:** For each $i < \omega$, $|E_i| < \aleph_0$. 

In this case, we can modify the partition $\mathcal{E}$ in such a way that we obtain a new partition $\mathcal{F} = \{F_i : i < \omega\}$ of $X_0$ constituted by closed subsets of $X$ with $|F_i| = 1$. We name $x_n$ the only element belonging to $F_n$ for each $n < \omega$. Now, we take a partition $A_0, A_1, \ldots, A_n, \ldots$ of $\omega$ where each $A_i$ is infinite. We define $C_k = \{x_n : n \in A_k\}$ for each $k < \omega$. The collections $\mathcal{F}$ and $\{C_k : k < \omega\}$ satisfy (2) and (3) in Proposition 2.3.

**Second case:** There is an infinite subset of natural numbers $J$ such that, for each $n \in J$, $|E_n| \geq \aleph_0$.

In this case, we modify partition $\mathcal{E}$ in such a way that we obtain a partition $\{H_i : i < \omega\}$ of $X_0$ of closed subsets of $X$ with $|H_i| \geq \aleph_0$ for every $i < \omega$. Now, let $\kappa_i$ be the cardinality of $H_i$ for each $i < \omega$. Let us list $H_i$ as $\{x_i^\lambda : \lambda < \kappa_i\}$ with $x_i^\lambda \neq x_i^\xi$ if $\lambda \neq \xi$. Of course $|X_0| = \kappa = \sup\{\kappa_i : i < \omega\}$. For each $\delta < \kappa$, we take $G_\delta = \{x_i^\lambda : \kappa_i > \delta\}$ and $T = \{\delta < \kappa : |G_\delta| = \aleph_0\}$.

If $\kappa \setminus T = \emptyset$, then $\{H_n : n < \omega\}$ and $\{G_\delta : \delta < \kappa\}$ satisfy the requirements.

Now, assume that $\kappa \setminus T \neq \emptyset$. For each $\delta \in \kappa \setminus T$, $G_\delta$ is a finite set $\{x_n^{\delta_i} \mid i < \omega\}$. We denote by $M_\delta$ the set of natural numbers $\{s_1, \ldots, s_t\}$ related with $G_\delta$. Let $\delta_0$ be the first element of $\kappa \setminus T$.

**Claim:** For each $\delta \in \kappa \setminus T$, $M_\delta \subset M_{\delta_0}$.

Indeed, let $\delta$ be an element of $\kappa \setminus T$ and $G_\delta = \{x_{s_1}^\delta, \ldots, x_{s_t}^\delta\}$. By definition of $G_\delta$, we have that $\delta < \kappa_{s_l}$ for every $l \in \{1, \ldots, t\}$. Since $\delta_0 \leq \delta$, $\delta_0 < \kappa_{s_l}$ for each $l \in \{1, \ldots, t\}$. Then, for each $l \in \{1, \ldots, t\}$, $x_{s_l}^\delta \in G_{\delta_0}$; that is, $s_l \in M_{\delta_0}$ for every $l \in \{1, \ldots, t\}$. We conclude that $M_\delta \subset M_{\delta_0}$.

Let $n_0$ be equal to the greatest element in $M_{\delta_0}$, and let us call $H$ the set $\bigcup_{n \leq n_0} H_n$. We partition $H$ in a family of infinite countable subsets:

$H = \bigcup_{\lambda < |H|} D_\lambda$, $|D_\lambda| = \aleph_0$ for all $\lambda < |H|$, and $D_\lambda \cap D_\xi = \emptyset$ for every $\lambda, \xi < |H|$ with $\lambda \neq \xi$. For each $\lambda < |H|$ we enumerate the elements of $D_\lambda$ as $\{z_1^\lambda, z_2^\lambda, \ldots, z_{n_0}^\lambda\}$ in such a way that $z_j^\lambda \neq z_i^\lambda$ if $j \neq i$.

We take $\mathcal{C}$ as the family $\{\bar{G}_\delta : \delta \in \delta_0 \setminus T \cup \{D_\lambda : \lambda < |H|\}\}$, where, for each $\delta \in \delta_0 \setminus T$, $\bar{G}_\delta = \{x_i^{\delta_i} \in G_\delta : i > n_0\}$.

Now, we are going to define the family $\mathcal{F}$. Let $F_1 = H_{n_0+1} \cup \{z_1^\lambda : \lambda < |H|\}, \ldots, F_k = E_{n_0+k} \cup \{z_k^\lambda : \lambda < |H|\}, \ldots$.

It is not difficult now to prove that families $\mathcal{F}$ and $\mathcal{C}$ satisfy properties (2) and (3) in Proposition 2.3.

**Third case:** There is $n_0 < \omega$ such that $\{n < \omega : |E_n| \geq \aleph_0\} \subset \{0, \ldots, n_0\}$.

In this case, we can modify partition $\mathcal{E}$ in such a way that we obtain a new partition $\{H_i : i < \omega\}$ of $X_0$ with each $H_i$ closed in $X$, $|H_0| \geq \aleph_0$ and $|H_n| = 1$ for every $n > 0$; say, $H_n = \{x_n\}$ for each $n > 0$.

We partition $H_0$ in a family of infinite countable subsets: $H_0 = \bigcup_{\lambda < |H_0|} D_\lambda$, where $D_\lambda = \{z_{i_1}^\lambda, z_{i_2}^\lambda, \ldots, z_{i_{n_0}}^\lambda\}$ in such a way that $z_{i_j}^\lambda \neq z_{i_i}^\lambda$ if $j \neq i$. For each $\lambda < |H_0|$, $|D_\lambda| = \aleph_0$ and $D_\lambda \cap D_\xi = \emptyset$ for every $\lambda, \xi < |H_0|$ with $\lambda \neq \xi$. For each $\lambda < |H_0|$ we enumerate the elements of $D_\lambda$ as $\{z_1^\lambda, z_2^\lambda, \ldots, z_{n_0}^\lambda\}$ in such a way that $z_j^\lambda \neq z_i^\lambda$ if $j \neq i$. Then, we define $F_1 = H_{n_0+1} \cup \{z_1^\lambda : \lambda < |H_0|\}, \ldots, F_{n_0} = H_{n_0+n_0} \cup \{z_{n_0}^\lambda : \lambda < |H_0|\}, \ldots$.

It is not difficult now to prove that families $\mathcal{F}$ and $\mathcal{C}$ satisfy properties (2) and (3) in Proposition 2.3.
\[ |D_\lambda| = \aleph_0 \ \text{for all } \lambda < |H_0|, \ \text{and } D_\lambda \cap D_\xi = \emptyset \ \text{for every } \lambda, \xi < |H_0| \ \text{with } \lambda \neq \xi. \]  
For each \( \lambda < |H_0| \) we enumerate the elements of \( D_\lambda \) as \( \{ z_1^\lambda, z_2^\lambda, \ldots, z_n^\lambda, \ldots \} \) in such a way that \( z_j^\lambda \neq z_i^\lambda \) if \( j \neq i \).

We take \( \mathcal{C} \) as the family \( \{ C \} \cup \{ D_\lambda : \lambda < |H_0| \} \), where \( C = \{ x_n : n > 0 \} \).

Now, we are going to define the family \( \mathcal{F} \). Let \( F_1 = H_1 \cup \{ z_1^\lambda : \lambda < |H_0| \}, \ldots, F_k = H_k \cup \{ z_k^\lambda : \lambda < |H_0| \}, \ldots \)

The families \( \mathcal{F} \) and \( \mathcal{C} \) satisfy properties (2) and (3) in Proposition 2.3.

We have already finished the proof. \( \square \)

### 2.5 Examples.

1. If the set \( X_0 \) of isolated points of a topological space \( X \) is countable (in particular, if \( X \) has countable cellularity) and \( \emptyset \neq X \setminus X_0 = X_1 \subset \text{cl}_X X_0 \), then \( C_\square(X) \cong \square \mathbb{R}^{X_0} \).

2. We then have \( C_\square(\beta \omega) \cong \square \mathbb{R}^\omega \). More generally, if \( \kappa \) is an infinite cardinal number of countable cofinality, and \( Y \) is a subset of uniform ultrafilters on \( \kappa \), then \( Y \subseteq \text{cl}_{\kappa \cup Y} \kappa \) and \( (\kappa \cup Y)_1 = Y \) is a \( G_\delta \) subset of \( \kappa \cup Y \); so, \( C_\square(\kappa \cup Y) \cong \square \mathbb{R}^\kappa \). Also, for every almost disjoint family \( A \) of \( \omega \), \( C_\square(\Psi(A)) \cong \square \mathbb{R}^\omega \).

3. Of course, if \( X \) is perfect, \( X_0 \subset F_\sigma \) in \( X \); so, spaces of a wide class fulfill the conditions in Theorem 2.4. In particular, if \( X \) is metrizable (or even semi-stratifiable or developable) and \( \emptyset \neq X_1 \subset \text{cl}_X X_0 \), then \( C_\square(X) \cong \square \mathbb{R}^{X_0} \).

4. In particular, for every countable ordinal number \( \alpha \), \( C_\square([0, \alpha)) \cong \square \mathbb{R}^\omega \).

5. On the other hand, \( [0, \omega_1) \) is a locally compact first countable orderable space such that its subset of isolated points is not an \( F_\sigma \)-subset, and the Michael line \( M \) is an hereditarily paracompact quasi-developable space such that \( M_0 = \{ \text{irrational numbers} \} \) is not an \( F_\sigma \)-subset of \( M \).

A way to obtain examples of spaces \( X \) which satisfy the conditions in Theorem 2.4, now that we have mentioned the Michael line, is the following: Take a dense-in-itself non-countable separable space \((X, T)\). Let \( Q \) be a countable dense subset of \( X \). We define a new space \((X_Q, T_Q)\) as follows: let \( X_Q = X \) and \( B \in T_Q \) if and only if \( B = C \cup D \) with \( C \in T \) and \( D \subset Q \) (see [E, p. 306]). The space \( X_Q \) satisfies conditions in Theorem 2.4, so \( C_\square(X_Q) \cong \square \mathbb{R}^\omega \). Observe that \((X_Q)_0 = Q\) and \((X_Q)_1 = X \setminus Q\).

4. Let \( Y \) be a space with \( \text{iw}(Y) = \aleph_0 \). So \( C_p(Y) \) is a dense-in-itself non-countable separable space \(([Ar])\). Let \( Q \) be a countable dense subset of \( C_p(Y) \). Because of the previous example we obtain: \( C_\square(C_p(Y) Q) \cong \square \mathbb{R}^\omega \).

When \( Y = \mathbb{R} \), the set \( Q \) of polynomials with rational coefficients is a countable dense subset of \( C_p(\mathbb{R}) \). Then, \( C_\square(C_p(\mathbb{R}) Q) \cong \square \mathbb{R}^\omega \).

For each \( x \in X \), we have denoted by \( \mathcal{N}(x) \) the system of neighborhoods of \( x \) in \( X \). We will use the symbol \( \mathcal{N}_0(x) \) to designate the set \( \{ V \cap X_0 : V \in \mathcal{N}(x) \} \).

Observe that if \( x \in \text{cl}_X X_0 \), \( \mathcal{N}_0(x) \) is a filter on \( X_0 \). We are going to obtain a converse of Theorem 2.4 when \( \mathcal{N}_0(x) \) is an ultrafilter for every \( x \in X_1 \). First we prove the following:
2.6 Proposition. If $X_0$ is an $F_\sigma$-subset of $X$, then $X_0$ is a-$\omega$-rwt $X^b$.

Proof: Let $\mathcal{F} = \{F_n : n < \omega\}$ be a partition of $X_0$ constituted by closed subsets of $X$. We are going to prove that $\mathcal{F}$ is a resolution of $X_0$ with respect to $X^b$. Let $p \in X^b$ and $V \in \mathcal{N}(p)$. Since $p \in \text{cl}_X(X_0)$, then $V \cap X_0 \neq \emptyset$. Let $A = \{n < \omega : F_n \cap V \neq \emptyset\}$, and assume that there exists $n_0 < \omega$ such that for all $n > n_0$, $V \cap F_n = \emptyset$. We know that $V \cap (X \setminus \bigcup_{n \leq n_0} F_n) \neq \emptyset$, but $V \cap (X \setminus \bigcup_{n \leq n_0} F_n) \cap X_0 = \emptyset$, which is not possible. So, $A$ must be infinite. □

2.7 Theorem. Let $\emptyset \neq X_1 \subset \text{cl}_X X_0$ and assume that $\mathcal{N}_0(x)$ is an ultrafilter on $X_0$ for each $x \in X_1$. Then the following assertions are equivalent.

1. $X_0$ is $F_\sigma$ in $X$.
2. $X_0$ is a-$\omega$-rwt $X_1$.
3. $C\boxempty(X) \cong \Box \mathbb{R}^{X_0}$ and $X_0$ is a-$\omega$-rwt $X_1$.

Proof: (1) $\Rightarrow$ (2): This is a consequence of Proposition 2.6.

(2) $\Rightarrow$ (1): Let $\{F_n : n < \omega\}$ be a resolution of $X_0$ with respect to $X_1$. Let us fix $n < \omega$ and suppose that there exists $x \in \text{cl}_F F_n \cap X_1$. That is, for each $V \in \mathcal{N}(x)$, we have $V \cap F_n \neq \emptyset$. Thus, for each $V \cap X_0 \in \mathcal{N}_0(x)$, $V \cap F_n = (V \cap X_0) \cap F_n \neq \emptyset$. Since $\mathcal{N}_0(x)$ is an ultrafilter, $F_n$ must belong to $\mathcal{N}_0(x)$. Let $V'$ be an element of $\mathcal{N}(x)$ such that $F_n = V' \cap X_0$. Then we obtain $F_m \cap V' = \emptyset$ when $n \neq m$. But this last assertion contradicts our hypotheses. Therefore, $F_n$ must be closed in $X$.

We obtain (1) $\Rightarrow$ (3) by Theorem 2.4 and Proposition 2.6, and (3) $\Rightarrow$ (2) is trivial. □

The statement "$X_0$ is a-$\omega$-rwt $X_1$" in (2) and (3) in the previous theorem cannot be replaced by the weaker proposition "$X$ is a-$\omega$-rwt $X_1$". In fact, let $\alpha$ be an infinite cardinal number with uncountable cofinality. Since $X = \beta\alpha$ is an $\aleph_0$-resolvable space, $X$ is a-$\omega$-rwt $X_1$ and $A_0(\beta\alpha)$ is open in $C\boxempty(\beta\alpha)$. Nevertheless, $X_0$ is not an $F_\sigma$-subset of $X$.

2.8 Problem. Assume that we have the same assumptions given in Theorem 2.7. Suppose also that $C\boxempty(X) \cong \Box \mathbb{R}^{X_0}$. Is $X_0$ then a-$\omega$-rwt $X_1$?

3. Spaces $C\boxempty(X)$ when $X_0$ is an $F_\sigma$-subset of $X$

In this section we are going to consider spaces $C\boxempty(X)$ when the set of isolated points of $X$, $X_0$, is an $F_\sigma$-subset of $X$ and $\emptyset \neq X \setminus \text{cl}_X X_0 = Z$. For example, for the subspace $Y = \{r \in \mathbb{R} : r \leq 0\} \cup \{1/n : n \in \mathbb{N}\}$ of $\mathbb{R}$, $Y_0 = \{1/n : n \in \mathbb{N}\}$ is an $F_\sigma$-subset of $Y$, $Y^b = \{0\}$ and $Z = \{r \in \mathbb{R} : r < 0\}$. As usual, $CN$ is the class of cardinal numbers, and for a cardinal number $\kappa$, $\kappa^+$ is the minimum cardinal number strictly greater than $\kappa$.

Observe that the product space $E(\kappa) = [0, \omega] \times D(\kappa)$ where $[0, \omega]$ is the space of ordinals $\leq \omega$ with its order topology, and $D(\kappa)$ is the discrete space of cardinality $\kappa$, satisfies the conditions in Theorem 2.4. Thus, by Corollary 1.7 and
Theorem 2.4, we have

\[ \square\mathbb{R}^\kappa \cong C\square(E(\kappa)) \cong \bigoplus_{\varphi \in C((E(\kappa))_1)} (\square\mathbb{R}^\kappa)_\varphi. \]

Since \((E(\kappa))_1\) coincides with \(D(\kappa)\), we have \(C((E(\kappa))_1) = \mathbb{R}^\kappa\). Furthermore, \(|C((E(\kappa))_1)| = 2^\kappa\). So we have proved:

3.1 Lemma. For each infinite cardinal \(\kappa\), \(\square\mathbb{R}^\kappa\) accepts a partition of \(2^\kappa\) clopen subsets, each of them homeomorphic to \(\square\mathbb{R}^\kappa\).

3.2 Definitions. A partition \(C\) of a topological space \(X\) is a homeomorphic clopen partition of \(X\) if each element of \(C\) is clopen and homeomorphic to \(X\).

The homeomorphic clopen partition number of \(X\), \(\text{hop}(X)\), is the cardinal number \(\min\{\kappa \in CN : \text{there is no homeomorphic clopen partition of } X \text{ of cardinality } \kappa\}\).

It is easy to see that \(\text{hop}(X) \leq |X|^+\) for every space \(X\).

3.3 Proposition. For each infinite cardinal \(\kappa\), \(\text{hop}(\square\mathbb{R}^\kappa) = (2^\kappa)^+\).

Proof: Because of Lemma 3.1, \((2^\kappa)^+ \leq \text{hop}(\mathbb{R}^\kappa)\). Moreover, \(\text{hop}(\mathbb{R}^\kappa) \leq |\mathbb{R}^\kappa|^+ = (2^\kappa)^+\); so, \(\text{hop}(\square\mathbb{R}^\kappa) = (2^\kappa)^+\).

3.4 Corollary. Let \(\tau\), \(\gamma\) and \(\kappa\) be infinite cardinals. Then

\[ \bigoplus_{\alpha < \kappa} (\square\mathbb{R}^\tau)_\alpha \cong \square\mathbb{R}^\gamma \iff \kappa \leq 2^\tau \text{ and } \gamma = \tau. \]

Proof: Suppose that \(\psi : \bigoplus_{\alpha < \kappa} (\square\mathbb{R}^\tau)_\alpha \rightarrow \square\mathbb{R}^\gamma\) is a homeomorphism. Let \(\alpha < \kappa\) and \(x \in (\square\mathbb{R}^\tau)_\alpha\). We have that the connected component of \(x\) in \(\bigoplus_{\alpha < \kappa} (\square\mathbb{R}^\tau)_\alpha\), \(\sigma_x \square\mathbb{R}^\tau\), must be homeomorphic to \(\sigma_{\psi(x)} \square\mathbb{R}^\gamma\). Then, because of Proposition 1.12, \(\tau = \gamma\). Therefore, since \(|\bigoplus_{\alpha < \kappa} (\square\mathbb{R}^\tau)_\alpha| = |\square\mathbb{R}^\gamma|\), \(\kappa \cdot 2^\tau = 2^\gamma = 2^\tau\); thus, \(\kappa \leq 2^\tau\).

Now, assume that \(\kappa \leq 2^\tau\) and \(\gamma = \tau\). By Proposition 3.3, we have \(\bigoplus_{\alpha < \kappa} (\square\mathbb{R}^\tau)_\alpha \cong \square\mathbb{R}^\tau\). Hence, \(\bigoplus_{\alpha < \kappa} (\square\mathbb{R}^\tau)_\alpha \cong \square\mathbb{R}^\gamma\).

As has been the custom in this article, for a space \(X\), we denote by \(X_0\) the set of isolated points of \(X\), \(X_1 = X \setminus X_0\), \(X_b = (\text{cl}_X X_0) \cap X_1 \neq \emptyset\) and \(Z = X \setminus \text{cl}_X X_0\). Our next result generalizes Proposition 1.6.

3.5 Proposition. Let \(X\) be a space such that \(X_0\) is \(F_\sigma\) and \(X_b \neq \emptyset \neq Z\). Then, the following assertions are equivalent.

1. \(Z\) is almost-\(\omega\)-resolvable.
2. \(X\) is an-\(\omega\)-rwr-\(X_1\).
3. \(A_0(X) = \{ f \in C(X) : f \mid X_1 \equiv 0 \}\) is a clopen subgroup of \(C\square(X)\).
PROOF: (1) ⇒ (2): Let $\mathcal{H} = \{H_n : n < \omega\}$ be a resolution of $Z$, and let $\mathcal{F} = \{F_n : n < \omega\}$ be a partition of $X_0$ constituted by closed subsets of $X$. We define $C_0 = H_0 \cup X_b \cup F_0$ and $C_i = H_i \cup F_i$ for $i \geq 1$. It happens that $C = \{C_n : n < \omega\}$ is a resolution of $X$ with respect to $X_1$.

(2) ⇒ (1): Let $C = \{C_n : n < \omega\}$ be a resolution of $X$ with respect to $X_1$. Then, $\mathcal{H} = \{C_n \cap Z : n < \omega\}$ is a resolution of $Z$.

The equivalence (2) ⇔ (3) is Proposition 1.6.

3.6 Corollary. If $X_0$ is an $F_\sigma$-subset of $X$, $X^b \neq \emptyset$ and $Z$ is almost-\(\omega\)-resolvable, then

$$C_{\square}(X) = \oplus_{\bar{x} \in \hat{C}(X_1)} A_{\bar{x}}(X).$$

3.7 Theorem. Let $X$ be a topological space with $X_0$ being an $F_\sigma$-subset of $X$ and $X^b \neq \emptyset$. If $Z$ is almost-\(\omega\)-resolvable, then $A_0^0(X) \cong \Box \mathbb{R}^{X_0}$ and $C_{\square}(X)$ is the free topological sum of $|\hat{C}(X_1)|$ copies of $\Box \mathbb{R}^{X_0}$.

PROOF: We take the subspace $X = X_0 \cup X^b$ of $X$. The set of isolated points of $Y$, $Y_0$, is an $F_\sigma$-subset of $Y$ and $Y_1$ is not empty; in fact, $Y_0 = X_0$ and $Y_1 = X^b$. Hence, $A_0^0(Y)$ is equal to $\{f \in C(Y) : f \upharpoonright X^b \equiv 0\}$. We claim that the natural projection $\pi_Y : A_0^0(X) \to A_0^0(Y)$ defined by $\pi_Y(f) = f \upharpoonright Y$ is a homeomorphism. By Lemma 1.2, $\pi_Y \upharpoonright A_0^0(X)$ is an embedding.

Let $h \in A_0^0(Y)$. We define $h' \in \mathbb{R}^X$ as $h'(z) = 0$ for every $z \in Z$ and $h' \upharpoonright Y = h$. Let $z \in Z = X_1 \setminus X^b$ and $\varepsilon > 0$. Since $Z$ is open in $X$ and $h'[Z] = \{0\} \subset (-\varepsilon, \varepsilon)$, $h'$ is continuous in $z$. Now let $z \in X^b$. By the continuity of $h$, there is an open neighborhood $W$ of $z$ in $X$ such that $h[W \cap Y] \subset (-\varepsilon, \varepsilon)$. Since $W = (W \cap Y) \cup (W \cap Z)$, $h'[W] \subset (-\varepsilon, \varepsilon)$. It is clear that $h' \in A_0^0(X)$ and $\pi_Y(h') = h$. Thus $\pi_Y[A_0^0(X)] = A_0^0(Y)$.

Because of Corollary 3.6, $C_{\square}(X) = \bigoplus_{\bar{x} \in \hat{C}(X_1)} (A_0^0(X))_{\bar{x}}$ where $(A_0^0(X))_{\bar{x}}$ is a copy of $A_0^0(X)$. Thus, $C_{\square}(X) \cong \bigoplus_{\bar{x} \in \hat{C}(X_1)} (A_0^0(Y))_{\bar{x}}$. On the other hand, $Y_0$ is an $F_\sigma$-subset of $Y$, $\emptyset \neq Y_1 \subset \text{cl}_Y Y_0$ and $Y_0 = X_0$; so $A_0^0(X) \cong A_0^0(Y) \cong \Box \mathbb{R}^{X_0}$ (Theorem 2.4).

As a consequence of the previous theorem and Corollary 3.4 we obtain:

3.8 Corollary. Assume that $X_0$ is an $F_\sigma$-subset of $X$, $X^b \neq \emptyset$ and $Z$ is almost-\(\omega\)-resolvable. Then $C_{\square}(X) \cong \Box \mathbb{R}^{X_0}$ if and only if $|\hat{C}(X_1)| \leq 2^{\aleph_0}$.

The following result is a consequence of Theorems 0.1 and 3.7.

3.9 Corollary. It is consistent with ZFC that for every space $X$ for which $X_0$ is an $F_\sigma$-subset and $X^b \neq \emptyset$, $C_{\square}(X) \cong \bigoplus_{\bar{x} \in \hat{C}(X_1)} (\Box \mathbb{R}^{X_0})_{\bar{x}}$, and $C_{\square}(X) \cong \Box \mathbb{R}^{X_0}$ if, in addition, $|\hat{C}(X_1)| \leq 2^{\aleph_0}$. 
It is known (see [CH]) that \(|C(X)| \leq (wX)^{\omega X} \leq 2^{d(X)}\) for every infinite space \(X\), where \(wX\) is the least cardinal of an open basis, and \(\omega X\) is the least \(\kappa\) for which each open cover of \(X\) has a subfamily with \(\kappa\) or fewer elements whose union is dense; so:

3.10 Corollary. Let \(X\) be a topological space satisfying: \(X_0\) is an \(F_\sigma\)-subset of \(X\), \(X^b \neq \emptyset\) and \(Z\) is almost-\(\omega\)-resolvable. If \((wX_1)^{\omega X_1} \leq 2^{|X_0|}\) (in particular, if \(w(X) \leq |X_0|\) or \(d(X_1) \leq |X_0|\)), then \(C\square(X) \cong \square \mathbb{R}^X\).

3.11 Examples.

1) Since every first countable space is almost-\(\omega\)-resolvable, \(C\square(X) \cong \square \mathbb{R}^X\) if \(X\) is semi-stratifiable or developable (metrizable), \(X^b \neq \emptyset\) and \(w(X) \leq |X_0|\).

2) We now use the ideas of Example 2.5.(3). Let \(X\) be an almost-\(\omega\)-resolvable separable space with a non-countable open subset \(A\) such that \(X \setminus \text{cl}_X A \neq \emptyset\). Let \(Q\) be a countable dense subset of \(A\). The space \(X_Q\) satisfies conditions in Corollary 3.10, so \(C\square(X_Q) \cong \square \mathbb{R}^\omega\). Observe that, in this case, \((X_Q)_0 = Q, (X_Q)^b = \text{cl}_X A \setminus Q\), and \(Z(X_Q) = X \setminus \text{cl}_X A \neq \emptyset\) which is an almost-\(\omega\)-resolvable space.

3) Because of the previous example, \(C\square(\mathbb{R}^2_Q) \cong \square \mathbb{R}^\omega\), where \(Q = \{(x, y) \in \mathbb{Q}^2 : y > 0\}\).

Now we are going to prove a generalization of Theorem 2.7.

3.12 Theorem. Let \(X\) be a space with \(X^b \neq \emptyset\) and \(Z\) being an almost-\(\omega\)-resolvable space. Assume that for each \(p \in X^b, \mathcal{N}_0(p)\) is an ultrafilter on \(X_0\). Then, the following assertions are equivalent.

1) \(X_0\) is \(F_\sigma\) in \(X\).

2) \(X_0\) is a-\(\omega\)-wrtr\(X^b\).

3) \(C\square(X)\) is a free topological sum of \(\leq |\widehat{C}(X_1)|\) copies of \(\square \mathbb{R}^X\) and \(X_0\) is a-\(\omega\)-wrtr\(X^b\).

4) \(A_0^\square(X)\) is open in \(C\square(X)\) and \(X_0\) is a-\(\omega\)-wrtr\(X^b\).

5) \(A_0^\square(X) \cong \square \mathbb{R}^X\) and \(X_0\) is a-\(\omega\)-wrtr\(X^b\).

Proof: The implication (1) \(\Rightarrow\) (2) is Proposition 2.6, (2) \(\Rightarrow\) (1) can be proved in a similar way to (2) \(\Rightarrow\) (1) in Theorem 2.7, and (1) \(\Rightarrow\) (5) is a consequence of Theorem 3.7.

(1) \(\Rightarrow\) (3): If \(X_0\) is \(F_\sigma\), then, using Theorem 3.7, we obtain that \(C\square(X)\) is a free topological sum of \(\leq |\widehat{C}(X_1)|\) copies of \(\square \mathbb{R}^X\). The remainder is obtained by Proposition 2.6.

(3) \(\Rightarrow\) (2), (4) \(\Rightarrow\) (2) and (5) \(\Rightarrow\) (2) are obvious.

(2) \(\Rightarrow\) (4): This is (2) \(\Rightarrow\) (3) in Theorem 2.7 plus Theorem 2.4 if \(Z = \emptyset\). Assume now that \(Z \neq \emptyset\). Since \(X_0\) is c-\(\omega\)-rcra\(X^b\), \(X\) is a-\(\omega\)-wrtr\(X_1\), and we have only to apply Proposition 3.5. □
We finish this section with the following result which summarizes everything we have obtained up to now in this section, plus Rudin’s and Lawrence’s results [Ru2], [La].

3.13 Corollary. Let $X$ be a topological space such that $X_0$ is an $F_\sigma$-subset of $X$, $\emptyset \neq X^b$ and $Z$ is almost-$\omega$-resolvable. Then:

1. $C_{\square}(X)$ is not normal if $|X_0| > \aleph_0$;
2. The Continuum Hypothesis implies that $C_{\square}(X)$ is paracompact if $|X_0| = \aleph_0$.

4. $\Sigma$-products and spaces $C_{\square}(X)$

We are now going to consider spaces $X$ with $|X_1| = 1$ and we will calculate $C_{\square}(X)$ for this kind of spaces. Recall that a filter $\mathcal{F}$ on a set $X_0$ is $\omega^+\text{-}complete$ if for every $\{F_n : n < \omega\} \subset \mathcal{F}$, the set $\bigcap_{n<\omega} F_n$ belongs to $\mathcal{F}$. For a filter $\mathcal{F}$ on a set $X_0$, we define $\Sigma_{\mathcal{F}\mathbb{R}} X_0$, $\Sigma_{**\mathcal{F}\mathbb{R}} X_0$, $\hat{\Sigma}_{\mathcal{F}\mathbb{R}} X_0$ in the following way:

\[
\Sigma_{\mathcal{F}\mathbb{R}} X_0 = \{f \in \mathbb{R}^X_0 : \{x \in X_0 : f(x) = 0\} \in \mathcal{F}\},
\]

\[
\Sigma_{**\mathcal{F}\mathbb{R}} X_0 = \{f \in \mathbb{R}^X_0 : \text{for all } \epsilon > 0, \{x \in X_0 : |f(x)| < \epsilon\} \in \mathcal{F}\},
\]

\[
\hat{\Sigma}_{\mathcal{F}\mathbb{R}} X_0 = \{f \in \mathbb{R}^X_0 : \text{for all } \epsilon > 0, \{x \in X_0 : |f(x)| \geq \epsilon\} \notin \mathcal{F}\}.
\]

For a filter $\mathcal{F}$ on $X_0$, $\Sigma_{\mathcal{F}\mathbb{R}} X_0 \subset \Sigma_{**\mathcal{F}\mathbb{R}} X_0 \subset \hat{\Sigma}_{\mathcal{F}\mathbb{R}} X_0$. When $\mathcal{F}$ is an ultrafilter, then $\Sigma_{**\mathcal{F}\mathbb{R}} X_0 = \hat{\Sigma}_{\mathcal{F}\mathbb{R}} X_0$.

The symbols $\Sigma_{\mathcal{F}\mathbb{R}} X_0$, $\Sigma_{**\mathcal{F}\mathbb{R}} X_0$, $\hat{\Sigma}_{\mathcal{F}\mathbb{R}} X_0$ mean that we are considering the sets $\Sigma_{\mathcal{F}\mathbb{R}} X_0$, $\Sigma_{**\mathcal{F}\mathbb{R}} X_0$, $\hat{\Sigma}_{\mathcal{F}\mathbb{R}} X_0$ with their box product topology.

Recall that for a space $X$, $X_0$ is the set of isolated points of $X$, $X_1 = X \setminus X_0$ and always $\emptyset \neq X_1 \subset \text{cl}_X X_0$.

We begin our analysis by obtaining some results about resolvability of $X$ when $|X_1| = 1$.

4.1 Proposition. Let $X$ be a space such that $X_1 = \{p\}$. Then, $X$ is a-$\omega$-rwrt $X_1$ iff $X_0$ is a-$\omega$-rwrt $X_1$.

Proof: Assume that $X$ is a-$\omega$-rwrt $X_1$ and let $\{F_n : n < \omega\}$ be a resolution of $X$ with respect to $X_1$. Let $n_0$ be a natural number such that $p \in F_{n_0}$. So, $\{F_n : n \in \omega \setminus \{n_0\}\} \cup \{F_{n_0} \cap X_0\}$ is a resolution of $X_0$ with respect to $X_1$. \qed

4.2 Proposition. Let $X_1 = \{p\}$, and assume that $N_0(p) = \{X_0 \cap N : N$ is a neighborhood of $p\}$ is a non-$\omega^+\text{-}complete$ filter. Then, $X_0$ is a-$\omega$-rwrt $X_1$.

Proof: Let $\{V_n : n < \omega\} \subset N_0(p)$ such that $\bigcap_{n<\omega} V_n \notin N_0(p)$ with $V_0 = X_0$. Let $W_n = \bigcap_{0 \leq n} V_n$, $F_0 = \bigcap_{n<\omega} W_n$ and $F_{n+1} = W_n \setminus W_{n+1}$. We are going to prove that $\{F_n : n < \omega\}$ is a resolution of $X_0$ with respect to $X_1$. 

Suppose the contrary; that is, assume that there are $V \in \mathcal{N}(p)$ and $n_0 < \omega$ such that $V \cap F_n = \emptyset$ for all $n \geq n_0$. We take $M_0 = W_{n_0+1} \cap V$. The set $M_0$ belongs to $\mathcal{N}(p)$ and $M_0 \cap F_n = \emptyset$ for all $n \geq n_0$. We claim that $M_0$ is contained in $\bigcap_{n>n_0} W_n$. In fact, if $x \in M_0$, then $x \in W_{n_0+1}$. If $x \notin W_{n_0+2}$, $x$ must belong to $F_{n_0+2}$, which is not possible. The same reasoning used in an inductive process gives us that $x$ must belong to $\bigcap_{n>n_0} W_n$. But $\mathcal{N}(p)$ is a filter, $M_0 \in \mathcal{N}(p)$ and $M_0 \subset \bigcap_{n>n_0} W_n = \bigcap_{n<\omega} W_n$; so, we obtain a contradiction. Thus $\{F_n : n < \omega\}$ is a resolution of $X_0$ with respect to $X_1$. \hfill \Box

As a consequence of Theorem 2.7 and Proposition 4.2 we can prove:

4.3 Theorem. If $\mathcal{N}_0(p)$ is an ultrafilter which is not an $\omega^+\text{-complete}$ filter, then $X_0$ is $F_\sigma$ in $X$ and $C_\square(X) \cong \square\mathbb{R}^{X_0}$.

So, for an infinite cardinal number $\kappa$, if $p \in \beta\kappa \setminus \kappa$ is not $\omega^+$-complete, and $\{p\} \cup \kappa$ is considered with its topology inherited from $\beta\kappa$, then

$$C_\square(\{p\} \cup \kappa) \cong \square\mathbb{R}^{\kappa}.$$ 

Now, we are going to see that the “$\Sigma$-products” defined at the beginning of this section are related to our study of $C_\square(X)$.

4.4 Proposition. If $X_1 = \{p\}$, then $A_0^\square(X) \cong \Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}$.

Proof: The range of the isomorphic embedding $\phi : A_0^\square(X) \rightarrow \mathbb{R}^{X_0}$ defined as $\phi(f) = f \mid X_0$ (see Lemma 1.2) is equal to $\Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}$. Indeed, if $\epsilon > 0$ and $f \in A_0^\square(X)$, there is $V \in \mathcal{N}(p)$ such that $f[V] \subset (-\epsilon, \epsilon)$. Thus, $V \cap X_0 \in \mathcal{N}_0(p)$ and $V \cap X_0 \subset \{x \in X : |f(x)| < \epsilon\}$. Therefore, $\{x \in X_0 : |f(x)| < \epsilon\} \in \mathcal{N}_0(p)$. This means that $f \mid X_0 \in \Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}$. Moreover, if $g \in \Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}$ and $g \in \mathbb{R}^X$ is such that $g : X_0 = g$ and $g(p) = 0$, then $g \in A_0^\square(X)$ and $\phi(g) = g$. \hfill \Box

4.5 Proposition. If $X_1 = \{p\}$ and $\mathcal{N}_0(p)$ is an $\omega^+$-complete filter, then

$$\Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0} = \Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}.$$ 

Proof: We only have to prove that $\Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0} \subset \Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}$. Let $F \in \Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}$, and for each $n < \omega$ we take $D_n = \{x \in X_0 : |f(x)| < \frac{1}{1^n}\}$. It is clear that $D_n \in \mathcal{N}_0(p)$ for all $n < \omega$. So, $\bigcap_{n<\omega} D_n \in \mathcal{N}_0(p)$. But $\bigcap_{n<\omega} D_n = \{x \in X_0 : f(x) = 0\}$. Therefore, $f \in \Sigma_{*\mathcal{N}_0(p)}\mathbb{R}^{X_0}$. \hfill \Box

Because of the last two propositions we obtain the following corollary.
4.6 Corollary. If $X_1 = \{p\}$ and $N_0(p)$ is an $\omega^+$-complete filter, then

$$A_0(X) \cong \Sigma_{N_0(p)}^\square \mathbb{R}^{X_0}.$$ 

So, if $X_1 = \{p\}$, then the following assertions hold.

(1) If $N_0(p)$ is an $\omega^+$-complete filter, and $X$ is a-\omega-wrtr $X_1$, then

$$C_{\square}(X) \cong \bigoplus_{x \in \mathbb{R}} \left[ \Sigma_{N_0(p)}^\square \mathbb{R}^{X_0} \right]_x.$$ 

(2) If $N_0(p)$ is a filter which is not $\omega^+$-complete, then

$$C_{\square}(X) \cong \bigoplus_{x \in \mathbb{R}} \left[ \Sigma_{N_0(p)}^\square \mathbb{R}^{X_0} \right]_x.$$ 

Now we are going to consider the one-point compactification $K(X_0)$ of the discrete space $X_0$. Let $p$ be the point of $K(X_0)$ which compactifies $X_0$.

4.7 Proposition. Let $X_1 = \{p\}$. Then, $X = K(X_0)$ if and only if, for every $A \in [X_0]^{N_0}$ and $V \in N(p)$, we have $A \cap V \neq \emptyset$.

4.8 Theorem. If $X = K(X_0)$, then $N(p)$ is not $\omega^+$-complete. So, in this case we have

$$C_{\square}(X) \cong \bigoplus_{x \in \mathbb{R}} \left[ \Sigma_{N_0(p)}^\square \mathbb{R}^{X_0} \right]_x.$$ 

Proof: Let $A \in [X_0]^{N_0}$ with $A = \{a_n : n < \omega\}$ and $a_n \neq a_m$ if $n \neq m$. The set $V_n = X_0 \setminus \{a_0, \ldots, a_n\}$ belongs to $N_0(p)$ for every $n < \omega$, and $\bigcap_{n < \omega} V_n \notin N_0(p)$.

In order to reduce (1) and (2) formulated after Corollary 4.6, we need to calculate the hop number of our "\Sigma-products".

4.9 Theorem. Let $X_1 = \{p\}$ and let $\kappa \geq \aleph_0$. If there is $A \in [X_0]^\kappa$ such that $X \setminus A \in N(p)$, then

$$\text{hop}(\Sigma_{N_0(p)}^\square \mathbb{R}^{X_0}) \geq (2^\kappa)^+$$ 

and

$$\text{hop}(\Sigma_{N_0(p)}^\square \mathbb{R}^{X_0}) \geq (2^\kappa)^+.$$ 

Proof: We will sketch the proof of the first inequality. The proof of the second inequality is similar. Let $A \in [X_0]^\kappa$ such that $X \setminus A \in N(p)$. Because of Proposition 3.3, there exists a clopen partition of $\square \mathbb{R}^A$ of cardinality $2^\kappa$ such that each of its elements is homeomorphic to $\square \mathbb{R}^A$. Let $\{A_\lambda : \lambda < 2^\kappa\}$ be such a partition. For
each $\lambda < 2^\kappa$ we take a homeomorphism $\psi_\lambda : A_\lambda \to \square^{R^A}$, and we take $B_\lambda \subset R^{X_0}$ such that $\pi_x(B_\lambda) = R$ if $x \notin A$ and $\pi_A[B_\lambda] = A_\lambda$. Now we define for $\lambda < 2^\kappa$, $C_\lambda = B_\lambda \cap \Sigma_{\lambda, N_0(p)} \, R^{X_0}$. The set $C_\lambda$ is a non-empty subset of $\Sigma_{\lambda, N_0(p)} \, R^{X_0}$ for each $\lambda < 2^\kappa$ because $X \setminus A \in \mathcal{N}(p)$. The function $\Psi_\lambda : C_\lambda \to \Sigma_{\lambda, N_0(p)} \, R^{X_0}$ defined by $\pi_A \circ \Psi_\lambda(f) = \psi_\lambda(f \upharpoonright A)$ and for $x \notin A$, $\pi_x \circ \Psi_\lambda(f) = f(x)$, is a homeomorphism. (The hypothesis $X \setminus A \in \mathcal{N}(p)$ also gives us the surjectivity of $\Psi_\lambda$.) Furthermore, it is possible to prove that $\{C_\lambda : \lambda < 2^\kappa\}$ is a clopen partition of $\Sigma_{\lambda, N_0(p)} \, R^{X_0}$.

As a consequence of Proposition 4.7 and Theorem 4.9 we have:

**4.10 Corollary.** Let $X_1 = \{p\}$ and $X \neq K(X_0)$. Then,

$$\text{hop}(\Sigma_{\lambda, N_0(p)} \, R^{X_0}) \geq (2^{\aleph_0})^+$$

and

$$\text{hop}(\Sigma_{\lambda, N_0(p)} \, R^{X_0}) \geq (2^{\aleph_0})^+.$$

For a set $S$, the “$\Sigma$-product” $\Sigma = \{f \in \mathbb{R}^S : \forall \varepsilon > 0, |\{x \in S : |f(x)| \geq \varepsilon\}| < \aleph_0\}$ of $\mathbb{R}^S$ coincides with the $\Sigma$-product $\Sigma_{\lambda, F_0} \, \mathbb{R}^S$, where $F_0$ is the Fréchet filter on $S$ ($F \in F_0$ iff $S \setminus F$ is finite). That is, $\Sigma = \Sigma_{\lambda, F_0} \, \mathbb{R}^S$ where $p$ is the point which compacts the discrete space $S$.

**4.11 Proposition.** Let $X = K(X_0)$. Then, $\text{hop}(\Sigma_{\lambda, N_0(p)} \, R^{X_0}) \geq (2^{\aleph_0})^+$.

**Proof:** We have already mentioned that $\Sigma_{\lambda, N_0(p)} \, R^{X_0}$ is equal to the subspace $\{f \in R^{X_0} : \forall \varepsilon > 0, |\{x \in X_0 : |f(x)| \geq \varepsilon\}| < \aleph_0\}$ of $\square^{R^X}$. Let us fix an infinite countable subset of $X_0$: $B = \{x_n : n < \omega\}$. The collection $\mathcal{F} = \{\{x_n\} : n < \omega\}$ is a partition of $B$. So, we can consider the clopen subgroup $E(\mathcal{F})$ of $\square^{R^X}$ defined by $\mathcal{F}$ (see the definition before Proposition 1.3). It is now easy to verify that $C = \Sigma_{\lambda, N_0(p)} \, R^{X_0} \cap E(\mathcal{F})$ is a non-empty clopen subgroup of $\Sigma_{\lambda, N_0(p)} \, R^{X_0}$. Thus, $\Sigma_{\lambda, N_0(p)} \, R^{X_0}$ can be expressed as the free topological sum of the cosets of the quotient group $G = \Sigma_{\lambda, N_0(p)} \, R^{X_0} / C$:

$$\Sigma_{\lambda, N_0(p)} \, R^{X_0} \cong \bigoplus_{D \in G} D \cong \bigoplus_{\beta < |G|} (C)_\beta.$$

Now, we are going to prove that $|G|$ is greater or equal to $2^{\omega}$. In fact, take an almost disjoint family $B$ of $B$ of cardinality $2^{\omega}$, and for each $T \in B$ we define $f_T : X_0 \to \mathbb{R}$ as

$$f_T(x) = \begin{cases} 
\frac{1}{2^{n-1}} & \text{if } x = x_n \text{ and } x_n \in T \\
0 & \text{otherwise.}
\end{cases}$$
It is clear that \( f_T \in \Sigma_{\ast,N_0(p)}^\square \mathbb{R}^{X_0} \). Furthermore, if \( T_1,T_2 \in \mathcal{B} \) are different, \( f_{T_1} - f_{T_2} \) does not belong to \( C \). In fact, since \( T_1 \setminus T_2 \) is an infinite set, there is a sequence \( \{n_k : k < \omega\} \) of natural numbers, strictly increasing, such that \( \{x_{n_k} : k < \omega\} \subset T_1 \setminus T_2 \). For each \( m < \omega \), there is \( k_m \) such that \( n_{k_m} > m \); so, \((f_{T_1} - f_{T_2})(x_{n_{k_m}}) = \frac{1}{2^{n_{k_m}}} \notin \left[ -\frac{1}{2^{n_{k_m}}}, \frac{1}{2^{n_{k_m}}} \right] \). Then, \( f_{T_1} - f_{T_2} \notin E_{0,m}(\mathcal{F}) \). Therefore, \( f_{T_1} - f_{T_2} \notin E_0(\mathcal{F}) \). We conclude that \( |G| \geq 2^\omega \).

Now, because of Theorem 4.8 and the facts we have already shown in this proof,

\[
C_{\square}(X) \cong \bigoplus_{\alpha < 2^{\aleph_0}} \Sigma_{\ast,N_0(p)}^\square \mathbb{R}^{X_0} \cong \bigoplus_{\alpha < 2^{\aleph_0} \cdot |G|} (C)_{\alpha} \cong \bigoplus_{\alpha < |G|} (C)_{\alpha} \cong \Sigma_{\ast,N_0(p)}^\square \mathbb{R}^{X_0}.
\]

This means that \( \text{ht}(\Sigma_{\ast,N_0(p)}^\square \mathbb{R}^{X_0}) \geq (2^{\aleph_0})^+ \). \( \square \)

Next, we summarize the results given in Theorem 4.8, Corollary 4.10, Proposition 4.11 and in formulas (1), (2) which appear after Corollary 4.6.

**4.12 Theorem.** Let \( X \) be a space with \( X_1 = \{p\} \). Then, the following propositions hold.

1. If \( N_0(p) \) is \( \omega^+ \)-complete and \( X \) is \( a\omega \)-rwrt \( X_1 \), then

\[
C_{\square}(X) \cong \Sigma_{\ast,N_0(p)}^\square \mathbb{R}^{X_0}.
\]

2. If \( N_0(p) \) is not \( \omega^+ \)-complete, then

\[
C_{\square}(X) \cong \Sigma_{\ast,N_0(p)}^\square \mathbb{R}^{X_0}.
\]

**4.13 Examples.**

1. Let \( \kappa \) be an infinite cardinal and let \( p \in \beta \kappa \setminus \kappa \). Consider the subspace \( X = \kappa \cup \{p\} \) of \( \beta \kappa \). If \( p \) is not \( \omega^+ \)-complete, then

\[
\Sigma_{\ast,p}^\square \mathbb{R}^\kappa \cong \square \mathbb{R}^\kappa
\]

(see Theorem 4.12.(2) and the remark after Theorem 4.3).

2. Let \( L_\kappa(X_0) = \{p\} \cup X_0 \) be the \( <\kappa^+ \)-Lindelöfication of the discrete space \( X_0 \) where \( p \notin X_0 \) (that is, every point in \( X_0 \) is isolated and a system of neighborhoods of \( p \) is \( \{V \subset L_\kappa(X_0) : p \in V \text{ and } |L_\kappa(X_0) \setminus V| < \kappa^+ \}\)). The filter \( N_0(p) \) is \( \omega^+ \)-complete, and if \( \text{cof}(|X_0|) > \kappa \), then \( L_\kappa(X_0) \) is \( a\omega \)-rwrt \( \{p\} \). Since \( \{p\} = (L_\kappa(X_0))_1, C_{\square}(L_\kappa(X_0)) \cong \Sigma_{\ast,N_0(p)}^\square \mathbb{R}^{X_0} \).

3. In particular, if \( |X_0| = \aleph_1 \), then the space of the real-valued continuous functions defined in the Lindelöfication of \( X_0 \) with the box product topology, \( C_{\square}(L(X_0)) \), is homeomorphic to the \( \Sigma \)-product \( \Sigma_{\ast,0}^\square \mathbb{R}^{\aleph_1} \) of \( \square \mathbb{R}^{\aleph_1} \) based on \( \hat{0} \) with the box product topology.

This last example raises the following problem:
4.14 Problem. Is $\Sigma^{\square}_0\mathbb{R}^\kappa$ homeomorphic to $\square\mathbb{R}^\kappa$ if $2^\omega = 2^{\omega_1}$?

The last results of this section take advantage, once more, of Theorem 2.7 in order to obtain relations between product spaces $\square\mathbb{R}^\kappa$ and their $\Sigma$-products, and they give positive answers to some variations of Problem 4.14.

For infinite cardinal numbers $\gamma$ and $\kappa$ with $\gamma \leq \kappa$, we define

$$\Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa = \{ f \in \square\mathbb{R}^\kappa : |\{ \lambda < \kappa : f(\lambda) \neq 0 \}| < \gamma \}.$$

4.15 Proposition. For uncountable cardinals $\gamma$ and $\kappa$ with $\gamma \leq \kappa$, $\text{cof}(\gamma) > \aleph_0$, and $\text{cof}(\kappa) = \aleph_0$, $\square\mathbb{R}^\kappa$ is homeomorphic to $\bigoplus_{\lambda < 2^\kappa} (\Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa)_\lambda$.

**Proof:** Let $Y = \{ g \in \kappa^\omega : |F| \geq \gamma \forall F \in g \}$. Take $X = \kappa \cup Y$ with its topology inherited from $\beta\kappa$. Since $\text{cof}(\kappa) = \aleph_0$, $\kappa (= X_0)$ is a $\omega$-wrt $X_1$. Then, Theorem 2.7 guarantees that $C^{\square}(X)$ is homeomorphic to $\square\mathbb{R}^\kappa$.

On the other hand, the isomorphic embedding $\phi$ from $A_0(X)$ to $\square\mathbb{R}^\kappa$, defined in Lemma 1.2, satisfies $\phi[A_0(X)] = \Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa$ (here we use the hypothesis $\text{cof}(\gamma) > \omega$). Moreover, $X$ is normal and $Y$ is closed in $X$, so $\hat{C}(Y) = C(Y)$. Since $Y$ is a compact space, $|C(Y)| = 2^\kappa$ (Proposition 1.14). Hence, by Corollary 1.7, $C^{\square}(X) \cong \bigoplus_{\lambda < 2^\kappa} (\Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa)_\lambda$.

As a consequence of the previous result we obtain:

4.16 Corollary. Let $\kappa$ and $\gamma$ be two cardinal numbers which satisfy the same properties given in the hypotheses of Proposition 4.15. Then, $\square\mathbb{R}^\kappa \cong \Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa$ iff $\text{hop}(\Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa) = (2^\kappa)^+$.  

4.17 Corollary. Let $\gamma < \kappa$, $\text{cof}(\kappa) = \omega$, $\text{cof}(\gamma) > \omega$. Assume that there is a cardinal number $\tau < \gamma$ such that $2^\tau = 2^\kappa$. Then, $\text{hop}(\Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa) = (2^\kappa)^+$ and $\square\mathbb{R}^\kappa \cong \Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa$.

**Proof:** We have that $\Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa$ is equal to $\Sigma^{\square}_{0,\gamma\mathbb{N}(p)}\mathbb{R}^X_0$ where $X$ is the $\gamma$-Lindelöfication of the discrete space of cardinality $\kappa$. Corollary 4.9 implies that $\text{hop}(\Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa) \geq (2^\tau)^+$. This inequality plus the hypothesis $2^\tau = 2^\kappa$ plus Proposition 4.15 imply $\square\mathbb{R}^\kappa \cong \Sigma^{\square}_{0,\gamma}\mathbb{R}^\kappa$.  

5. Spaces $C^{\square}(X)$ when $X$ is countably compact

We have already pointed out that for a set $S$ the "$\Sigma$-product" $\Sigma = \{ f \in \mathbb{R}^S : \forall \epsilon > 0, |\{ x \in S : |f(x)| \geq \epsilon \}| < \aleph_0 \}$ of $\mathbb{R}^S$, coincides with the $\Sigma$-product.
\[ \Sigma_{*,\mathcal{F}_0} \mathbb{R}^S \] where \( \mathcal{F}_0 \) is the Fréchet filter on \( S \) (\( F \in \mathcal{F}_0 \) iff \( S \setminus F \) is finite). That is, \( \Sigma \) is equal to \( \Sigma_{*,\mathcal{N}(p)} \mathbb{R}^S \) where \( p \) is the point which compactifies the discrete space \( S \). Recall that for a topological space \( X \), \( X_0 \) is its subset of isolated points, \( X_1 = X \setminus X_0 \), \( X^b = X_1 \cap \text{cl}_X X_0 \) and \( Z = X_1 \setminus X^b \). Moreover, every space \( X \) in this article satisfies \( X_0 \neq \emptyset \neq X^b \).

5.1 Proposition. Let \( X \) be such that every infinite subspace of \( X_0 \) has a cluster point in \( X \). Then \( A_0(X) \) is homeomorphic to \( \Sigma_{*,\mathcal{F}_0} \mathbb{R}^{X_0} \).

Proof: It is easy to verify that the range of the isomorphic embedding \( \phi : A_0(X) \to \square \mathbb{R}^{X_0} \) (see Lemma 1.2) coincides with \( \Sigma_{*,\mathcal{F}_0} \mathbb{R}^{X_0} \). \( \square \)

5.2 Theorem. Let \( X \) be such that every infinite subset of \( X_0 \) has a cluster point in \( X \), and such that \( X \) is a-\( \omega \)-rwrt \( X_1 \). Then \( C(X) \) is homeomorphic to \( \bigoplus_{x \in \overline{C}(X_1)} (\Sigma_{*,\mathcal{F}_0} \mathbb{R}^{X_0})_x \). In particular, \( C(X) \cong \Sigma_{*,\mathcal{F}_0} \mathbb{R}^{X_0} \) if \( |\overline{C}(X_1)| \leq 2^\omega \).

Proof: Since \( X \) is a-\( \omega \)-rwrt \( X_1 \), \( A_0(X) \) is clopen in \( C(X) \). So,

\[
C(X) \cong \bigoplus_{x \in \overline{C}(X_1)} A_x(X) \cong \bigoplus_{x \in \overline{C}(X_1)} (\Sigma_{*,\mathcal{F}_0} \mathbb{R}^{X_0})_x
\]

(Proposition 5.1). The last assertion follows from Proposition 4.11. \( \square \)

Since every countably compact space is almost-\( \omega \)-resolvable, the following result is a consequence of the previous theorem.

5.3 Corollary. If \( X \) is a countably compact space, then

\[
C(X) \cong \bigoplus_{x \in \overline{C}(X_1)} (\Sigma_{*,\mathcal{F}_0} \mathbb{R}^{X_0})_x
\]

If in addition \( |\overline{C}(X_1)| \leq 2^\omega \), we obtain \( C(X) \cong \Sigma_{*,\mathcal{F}_0} \mathbb{R}^{X_0} \).

Observe that if \( X \) is a pseudocompact space and \( N \) is an infinite countable subset of \( X_0 \), hence \( N \) must have a cluster point in \( X \). So, it is natural to ask:

5.4 Problem. Is \( X \) a-\( \omega \)-rwrt \( X_1 \) if \( X \) is a pseudocompact space?

5.5 Corollary. (1) For every infinite cardinal number \( \kappa \), \( C(\beta\kappa) \) is homeomorphic to \( \bigoplus_{\lambda < 2^\kappa} (\Sigma_{*,\mathcal{F}_0} \mathbb{R}^\kappa)_\lambda \).

(2) For every \( \varrho \in \omega^* \), \( \square \mathbb{R}^\varrho \cong \Sigma_{*,\mathcal{F}_0} \mathbb{R}^\varrho \cong \Sigma_{*,\varrho} \mathbb{R}^\varrho \).

Proof: Assertion (1) follows from Corollary 5.3 and from the equalities: \( (\beta\kappa)_1 = \kappa^* \), \( \breve{C}(\kappa^*) = C(\kappa^*) \), \( w(\kappa^*) = 2^\kappa \) and (by Proposition 1.14) \( |C(\kappa^*)| = w(\kappa^*)^\omega = 2^\kappa \).

Assertion (2) is implied by Theorem 2.7 and Corollary 5.3. \( \square \)

Again, using Proposition 1.14, we will prove the following lemma.
5.6 Lemma. For every infinite ordinal number \( \alpha \), \( |C([0, \alpha])| = |\alpha|^\omega \).

Proof: For every ordinal number \( \alpha \), the space \([0, \alpha] \) is compact; so, \( |C([0, \alpha])| = |\alpha|^\omega \) by Proposition 1.14. If \( \alpha \) is a successor ordinal, \([0, \alpha] \) is compact and, again, \( |C([0, \alpha])| = |\alpha|^\omega \). Moreover, if \( \alpha \) is a limit ordinal with uncountable cofinality, then \( |C([0, \alpha])| = |C([0, \alpha])| = |\alpha|^\omega \).

Now, we only have to prove the equality \( |C([0, \alpha])| = |\alpha|^\omega \) when \( \alpha \) is a limit ordinal with countable cofinality. In this case, if \( \alpha_0 < \alpha_1 < \cdots < \alpha_n < \cdots \) and \( \sup\{\alpha_n : n < \omega \} = \alpha \), thus \( C([0, \alpha]) \supseteq \prod_{n<\omega} C((\alpha_n, \alpha_{n+1}) \). Then, \( |C([0, \alpha])| \leq \prod_{n<\omega} |C([0, \alpha_n])| \leq \prod_{n<\omega} |\alpha_n|^\omega \leq |\alpha|^\omega \).

On the other hand, \( |\alpha|^\omega = |C([0, \alpha])| \leq |C([0, \alpha])| \) because the relation \( f \rightarrow f \upharpoonright [0, \alpha] \) is a one-to-one function from \( C([0, \alpha]) \) to \( C([0, \alpha]) \).

So, the following results are a consequence of Corollary 5.3 and Lemma 5.6.

5.7 Corollary. Let \( \alpha \) be an infinite ordinal. Then,

1. \( C_{\square}(\omega, \alpha) \cong \bigoplus_{\lambda<|\alpha|} (\sum_{\square} \mathcal{F}_\lambda R^{\mathbb{N}})^\lambda \);
2. \( C_{\square}([0, \alpha]) \cong \bigoplus_{\lambda<|\alpha|} (\sum_{\square} \mathcal{F}_\lambda R^{\mathbb{N}})^\lambda \) if \( \text{cof}(\alpha) > \aleph_0 \);
3. \( \square R^{\mathbb{N}} \cong C_{\square}([0, \omega]) \) and \( \square([0, \omega]) = C_{\square}([0, \omega_1]) \cong (\sum_{\square} \mathcal{F}_\lambda R^{\mathbb{N}})^{\aleph_1} \).

Observe that the connected component of a point \( x \) in \( \sum_{\square} \mathcal{F}_\lambda R^{\mathbb{N}} \) is homeomorphic to \( \sigma_{\square} R^{\mathbb{N}} \). By Proposition 1.12 and the previous results we obtain:

5.8 Corollary. Let \( \alpha \) and \( \beta \) be two infinite ordinals, both with cofinality different from \( \aleph_0 \). Then, \( C_{\square}(\omega, \alpha) \cong C_{\square}([0, \beta]) \) if and only if \( |\alpha| = |\beta| \).

Consider the set
\[
\sum_{\square} \mathcal{F}_\lambda R^{\mathbb{N}} = \{ f \in R^{\mathbb{N}} : \text{ for all } \varepsilon > 0 \text{ and } \beta < \lambda, \quad |\{ \lambda < \beta : |f(\lambda)| \geq \varepsilon \}| < \aleph_0 \}.
\]

We denote this set with its box topology by \( \sum_{\square} \mathcal{F}_\lambda R^{\mathbb{N}} \). We leave the proof of the following result to the reader.

5.9 Proposition. Let \( \alpha \) be an ordinal number such that \( |\alpha| > \aleph_0 \) and \( \text{cof}(\alpha) = \aleph_0 \). Then,
\[
C_{\square}(\omega, \alpha) \cong \bigoplus_{\lambda<|\alpha|} (\sum_{\square} \mathcal{F}_\lambda R^{\mathbb{N}})^\lambda \).
\]
