# On graph associated to co-ideals of commutative semirings 

Yahya Talebi, Atefeh Darzi

#### Abstract

Let $R$ be a commutative semiring with non-zero identity. In this paper, we introduce and study the graph $\Omega(R)$ whose vertices are all elements of $R$ and two distinct vertices $x$ and $y$ are adjacent if and only if the product of the co-ideals generated by $x$ and $y$ is $R$. Also, we study the interplay between the graph-theoretic properties of this graph and some algebraic properties of semirings. Finally, we present some relationships between the zero-divisor graph $\Gamma(R)$ and $\Omega(R)$.

Keywords: semiring; co-ideal; maximal co-ideal
Classification: 16Y60, 05C75

## 1. Introduction

The concept of the zero-divisor graph of a commutative ring $R$ was first introduced by Beck [3]. He defined this graph as a simple graph where all elements of the ring $R$ are the vertex-set of this graph and two distinct elements $x$ and $y$ are adjacent if and only if $x y=0$. Beck conjectured that $\chi(R)=\omega(R)$ for every ring $R$. In [2], Anderson and Livingston introduced the zero-divisor graph with vertices $Z(R)^{*}=Z(R) \backslash\{0\}$, the set of non-zero zero-divisors of $R$. Some other investigations into properties of zero-divisor graph over commutative semiring may be found in [5], [6]. In [11], Sharma and Bhatwadekar defined another graph on a ring $R$ with vertices as elements of $R$ and there is an edge between two distinct vertices $x$ and $y$ in $R$ if and only if $R x+R y=R$. Further, in [10], Maimani et al. studied the graph defined by Sharma and Bhatwadekar and called it comaximal graph. Also, in [1], Akbari et al. studied the comaximal graph over non-commutative ring.

Note that throughout this paper all semirings are considered to be commutative semirings with non-zero identity. First, we introduce the concept of product of coideals in the semiring $R$. Next, we define an undirected graph over commutative semiring in which vertices are all elements of $R$ and two distinct vertices $x$ and $y$ are adjacent if and only if the product of the co-ideals generated by $x$ and $y$ is $R$ (i.e. $F(x) F(y)=R$ ). We denote this graph by $\Omega(R)$. In Section 2, we recall some notions of semirings which will be used in this paper. In other sections, we study some graph-theoretic properties of $\Omega(R)$ and its subgraphs such as diameter, radius, girth, clique number and chromatic number.

In a graph $G$, we denote the vertex-set of $G$ by $V(G)$ and the edge-set by $E(G)$. A graph $G$ is said to be connected, if there is a path between every two distinct vertices and we say that $G$ is totally disconnected, if no two vertices of $G$ are adjacent. For a given vertex $x$, the number of all vertices adjacent to it, is called degree of the vertex $x$, denoted by $\operatorname{deg}(x)$. For distinct vertices $x$ and $y$ of $G$, let $d(x, y)$ be the length of the shortest path from $x$ to $y(d(x, x)=0$ and $d(x, y)=\infty$ if there is no such path). The diameter of $G$ is $\operatorname{diam}(G)=\sup \{d(x, y): x$ and $y$ are distinct vertices of $G\}$. The girth of $G$, denoted by $\operatorname{gr}(G)$, is defined as the length of the shortest cycle in $G$. If $G$ has no cycles, then $\operatorname{gr}(G)=\infty$ and $G$ is called a forest. Also, $G$ is called a tree if $G$ is connected and has no cycles. A clique in a graph $G$ is a complete subgraph of $G$. The clique number of $G$, denoted by $\omega(G)$, is the number of vertices in a largest clique of $G$. An independent set in a graph $G$ is a set of pairwise non-adjacent vertices. A graph in which each pair of distinct vertices is joined by an edge is called a complete graph. We denote the complete graph on $n$ vertices by $K_{n}$. For a positive integer $k$, a $k$-partite graph is one whose vertex-set can be partitioned into $k$ independent sets. A $k$-partite graph $G$ is said to be a complete $k$-partite graph, if each vertex is joined to every vertex that is not in the same partition. The complete bipartite graph (2-partite graph) with parts of sizes $m$ and $n$ is denoted by $K_{m, n}$. We will sometimes call a $K_{1, n}$ a star graph. We write $G \backslash\{x\}$ or $G \backslash S$ for the subgraph of $G$ obtained by deleting a vertex $x$ or set of vertices $S$. An induced subgraph is a subgraph obtained by deleting a set of vertices. Also, a spanning subgraph of $G$ is a subgraph with vertex-set $V(G)$. A general reference for graph theory is [12].

## 2. Preliminaries

In this section, we recall various notions about semirings which will be used throughout the paper. A semiring $R$ is an algebraic system $(R,+, \cdot)$ such that $(R,+)$ is a commutative monoid with identity element 0 and $(R, \cdot)$ is a semigroup. In addition, operations + and $\cdot$ are connected by distributivity and 0 annihilates $R$ (i.e. $x 0=0 x=0$ for each $x \in R$ ). A semiring $R$ is said to be commutative if $(R, \cdot)$ is a commutative semigroup and $R$ is said to have an identity if there exists $1 \in R$ such that $1 x=x 1=x$.

Recall that, throughout this paper, all semirings are commutative with nonzero identity. The following definitions are given in [7], [9].
2.1 Definition. Let $R$ be a semiring.
(1) A non-empty subset $I$ of $R$ is called a co-ideal of $R$ if and only if it is closed under multiplication and satisfies the condition that $a+r \in I$ for all $a \in I$ and $r \in R$. According to this definition, $0 \in I$ if and only if $I=R$. Also, a co-ideal $I$ of $R$ is called strong, if $1 \in I$.
(2) A co-ideal $I$ of semiring $R$ is called subtractive if $x \in I$ and $x y \in I$, implies $y \in I$ for all $x, y \in R$. So every subtractive co-ideal is a strong co-ideal.
(3) A proper co-ideal $P$ of $R$ is called prime if $a+b \in P$, implies $a \in P$ or $b \in P$ for all $a, b \in R$.
(4) A proper co-ideal $I$ of $R$ is called maximal if there is no co-ideal $J$ such that $I \subset J \subset R$.
(5) An element $a$ of a semiring $R$ is multiplicatively idempotent if and only if $a^{2}=a$ and $a$ is called additively idempotent if and only if $a+a=a$. A semiring $R$ is said to be idempotent if it is both additively and multiplicatively idempotent.
(6) An element $x$ of a semiring $R$ is called a zero-sum of $R$, if there exists an element $y \in R$ such that $x+y=0$. It is clear that, $y$ is the unique element which satisfies $x+y=0$. We will denote the set of all zero-sums of $R$ by $Z S(R)$. It is easy to see that $Z S(R)$ is an ideal of $R$. Also, a semiring $R$ is a ring if and only if $Z S(R)=R$ and $R$ is called zero-sumfree if and only if $Z S(R)=0$.
(7) If $A$ is a non-empty subset of a semiring $R$, then the set $F(A)$ of all elements of $R$ of the form $a_{1} a_{2} \ldots a_{n}+r$, where $a_{i} \in A$ for all $1 \leq i \leq n$ and $r \in R$, is a co-ideal of $R$ containing $A$. In fact, $F(A)$ is the unique smallest co-ideal of $R$ containing $A$.

By the above definition, we can consider the co-ideal generated by a single element $x \in R$ as follows: $F(x)=\left\{x^{n}+r: r \in R\right.$ and $\left.n \in \mathbf{N}\right\}$. It is obvious that, if $x \in I$ for some co-ideal $I$, then $F(x) \subseteq I$.

By definition of co-ideal, if $R$ is a ring, then $R$ has no proper co-ideals and so throughout this paper we consider semirings which are not rings. For a semiring $R$, we denote the set of maximal co-ideals, the union of all the maximal co-ideals and the intersection of all the maximal co-ideals of $R$ by $C o-\operatorname{Max}(R), U M(R)$ and $I M(R)$, respectively. Also, if the semiring $R$ has exactly one maximal coideal, then we say that the semiring $R$ is $c$-local and $R$ is said to be a $c$-semilocal semiring, if $R$ has only a finite number of maximal co-ideals.
2.2 Lemma ([7]). Let $I_{1}, \ldots, I_{n}$ be co-ideals of a semiring $R$ and $P$ be a prime co-ideal containing $\bigcap_{i=1}^{n} I_{i}$. Then $I_{i} \subseteq P$ for some $i=1, \ldots, n$. Moreover, if $P=\bigcap_{i=1}^{n} I_{i}$, then $P=I_{i}$ for some $i$.
2.3 Lemma. Let $R$ be a semiring. Then $x \in \sqrt{Z S(R)}$ if and only if $F(x)=R$.

Proof: Let $x \in \sqrt{Z S(R)}$. Thus $x^{n} \in Z S(R)$ for some positive integer $n$. This implies $x^{n}+r=0$ for some $r \in R$. Hence $0 \in F(x)$, since $x^{n}+r \in F(x)$ and so $F(x)=R$.

The converse follows, since all conclusions are reversible.
2.4 Proposition. Let $R$ be a semiring. Then $R \backslash \sqrt{Z S(R)}=U M(R)$.

Proof: Assume that $x \in R \backslash \sqrt{Z S(R)}$. Thus $F(x) \neq R$ and by [7, Proposition 2.1], there exists $m \in C o-\operatorname{Max}(R)$ such that $x \in F(x) \subseteq m$. Hence $R \backslash \sqrt{Z S(R)} \subseteq U M(R)$.

Conversely, suppose that $x \in U M(R)$. Thus there is a maximal co-ideal $m$ such that $x \in m$. Now, if $x \in \sqrt{Z S(R)}$, then $F(x)=R$ by Lemma 2.3 and so $R=F(x) \subseteq m$, that is impossible. Hence $U M(R) \subseteq R \backslash \sqrt{Z S(R)}$. This implies $R \backslash \sqrt{Z S(R)}=U M(R)$.
2.5 Remark. Note that the Prime Avoidance Theorem is explained for subtractive prime co-ideals of a commutative semiring $R$ in [4, Theorem 3.8]. Also, by [8, Proposition 2.5] and [7, Theorem 3.10], every maximal co-ideal is a subtractive and prime co-ideal, so we can conclude that the Prime Avoidance Theorem and Lemma 2.2 also hold for the case where co-ideals are maximal.

In the following, we define the product of co-ideals of a semiring $R$. It is straightforward to verify that the product of co-ideals with this definition is a coideal.
2.6 Definition. Let $I$ and $J$ be two co-ideals of a semiring $R$. We define the product of $I$ and $J$ as follows:

$$
I J=\{x y+r: x \in I, y \in J \text { and } r \in R\} .
$$

Similarly, we define the product of any finite family of co-ideals. Moreover, $I^{n}$ is defined for any co-ideal $I$ and $I^{n}=\left\{a_{1} \ldots a_{n}+r: a_{i} \in I\right.$ and $\left.r \in R\right\}$.

Let $I$ and $J$ be co-ideals of $R$ such that $x \in I$ and $y \in J$. Note that with this definition, if $I$ and $J$ are strong co-ideals, then $x, y \in I J$ because $x=x 1+0$ and $y=1 y+0$ but this may not be true in general.

## 3. Some basic properties of $\Omega(R)$

As mentioned in the introduction, the graph $\Omega(R)$ is a graph with all the elements of $R$ as its vertex-set and two distinct vertices $x$ and $y$ are adjacent if and only if $F(x) F(y)=R$. Let $\Omega_{1}(R)$ be the subgraph of $\Omega(R)$ with vertexset $\sqrt{Z S(R)}$ and $\Omega_{2}(R)$ be the subgraph of $\Omega(R)$ with vertex-set $U M(R)$. If $x \in \sqrt{Z S(R)}$, then by Lemma 2.3, $F(x)=R$ and this implies $x$ is adjacent to any other vertex of $R$. With this comment, we can say that $\Omega_{1}(R)$ is a complete graph. Also, if $x, y \in m$ for some maximal co-ideal $m$ of $R$, then $x$ and $y$ cannot be adjacent because $F(x) F(y) \subseteq m$. Hence, if the semiring $R$ has one maximal co-ideal, then $\Omega_{2}(R)$ is a totally disconnected graph.
3.1 Lemma. Let $m$ be a maximal co-ideal of a semiring $R$ and $x \in R$. If $x \notin m$, then $m F(x)=R$.

Proof: Suppose that $x \notin m$. Thus $F(m \cup\{x\})=R$ since $m \subsetneq F(m \cup\{x\})$ and $m$ is a maximal co-ideal. Now, since $0 \in R$, we split the proof into three cases for $F(m \cup\{x\})$ :

Case 1: There exist $a_{1}, \ldots, a_{k} \in m$ and $r \in R$ for some positive integer $k$ such that $a_{1} \ldots a_{k}+r=0$. This implies $0 \in m$ since $m$ is co-ideal. This is a contradiction because $m$ is a maximal co-ideal.

Case 2: $x^{t}+r=0$ for some $r \in R$ and a positive integer $t$. In this case, $F(x)=R$ because $0=x^{t}+r \in F(x)$ and so $m F(x)=R$.

Case 3: $y x^{t}+r=0$ for some $y \in m, r \in R$ and a positive integer $t$. Hence $m F(x)=R$ since $0=y x^{t}+r \in m F(x)$.

As an immediate consequence of Lemma 3.1, we have the next proposition:
3.2 Proposition. Let $m$ be a maximal co-ideal of a semiring $R$ and $x \in R$. If $x \notin m$, then there is an element $y \in m$ such that $x$ is adjacent to $y$ in $\Omega(R)$.

Proof: Suppose that $m$ is a maximal co-ideal and $x \notin m$. By Lemma 3.1, we have $m F(x)=R$. This implies $y\left(x^{t}+r\right)+k=0$ for some $r, k \in R, y \in m$ and a positive integer $t$. Hence $y x^{t}+s=0$ for some $s \in R$ and so $F(x) F(y)=R$ since $0=y x^{t}+s \in F(x) F(y)$. Therefore, $x$ and $y$ are adjacent in $\Omega(R)$.
3.3 Proposition. Let $R$ be a semiring and $x \in R$. Then $x \in I M(R)$ if and only if $x$ is adjacent to no vertex of $\Omega_{2}(R)$.

Proof: Let $x \in I M(R)$. Assume contrary that $y \in U M(R)$ is adjacent to $x$ in $\Omega_{2}(R)$. Thus there exists $m \in C o-\operatorname{Max}(R)$ such that $y \in m$ and $F(x) F(y)=R$. On the other hand, $x \in I M(R)$ gives $x \in m$. Hence $F(x) F(y) \subseteq m$, that is a contradiction.

Conversely, assume that $x$ is not adjacent to any vertex of $\Omega_{2}(R)$. If $x \notin$ $I M(R)$, there exists $m \in C o-\operatorname{Max}(R)$ such that $x \notin m$. By Proposition 3.2, there is an element $y \in m$ such that $x$ is adjacent to $y$, which is contrary to our assumption.

By Proposition 3.3, for each $x \in I M(R)$, $\operatorname{deg}_{\Omega_{2}(R)}(x)=0$. So it will be interesting to study the properties of the graph $\Omega_{2}(R) \backslash I M(R)$ with vertex-set $U M(R) \backslash I M(R)$. Note that if $R$ is a c-local semiring, then $\Omega_{2}(R) \backslash I M(R)$ is an empty graph.
3.4 Theorem. Let $R$ be a semiring which is not c-local. Then $\Omega_{2}(R) \backslash I M(R)$ is a complete bipartite graph if and only if $R$ has exactly two maximal co-ideals.

Proof: First, assume that $\Omega_{2}(R) \backslash I M(R)$ is a complete bipartite graph with vertex-sets $V_{1}$ and $V_{2}$. Clearly, $m$ is contained in one of the partitions for any maximal co-ideal $m$. Thus, suppose that $m_{i} \backslash I M(R) \subseteq V_{i}$ for $i=1,2$. If $R$ has another maximal co-ideal such as $m_{3}$, then $m_{3} \backslash I M(R) \subseteq V_{i}$ for some $i=1,2$, which is impossible, since $m_{1} m_{3}=m_{2} m_{3}=R$. Hence $R$ can have only two maximal co-ideals.

Conversely, suppose that $C o-\operatorname{Max}(R)=\left\{m_{1}, m_{2}\right\}$. Then the vertex-set of $\Omega_{2}(R) \backslash I M(R)$ is $\left(m_{1} \backslash m_{2}\right) \cup\left(m_{2} \backslash m_{1}\right)$. Clearly, the subgraphs $m_{1} \backslash m_{2}$ and $m_{2} \backslash m_{1}$ are totally disconnected. Let $x \in m_{1} \backslash m_{2}$ and $y \in m_{2} \backslash m_{1}$. Now to complete the proof, it suffices to show that $F(x) F(y) \nsubseteq m_{1}$ and $F(x) F(y) \nsubseteq m_{2}$. If $F(x) F(y) \subseteq m_{1}$, then $x y \in m_{1}$. This implies that $y \in m_{1}$, since $m_{1}$ is subtractive, a contradiction. Similarly, it can be shown that $F(x) F(y) \nsubseteq m_{2}$. Therefore we have $F(x) F(y)=R$. Hence $\Omega_{2}(R) \backslash I M(R)$ is complete bipartite graph with vertex-set $m_{1} \backslash m_{2}$ and $m_{2} \backslash m_{1}$.

In the following, we give an example of semiring $R$ in which $R$ has two maximal co-ideals and show that $\Omega_{2}(R) \backslash I M(R)$ is complete bipartite graph.
3.5 Example. Let $S=\{0,1, a\}$ be an idempotent semiring in which $a+1=$ $1+a=a$ and let $R=S \times S$. The maximal co-ideals of $R$ are as follows:

$$
\begin{aligned}
m_{1} & =\{(0,1),(0, a),(1, a),(a, 1),(1,1),(a, a)\} \\
m_{2} & =\{(1,0),(a, 0),(1, a),(a, 1),(1,1),(a, a)\}
\end{aligned}
$$

It can be shown that $\Omega_{2}(R) \backslash I M(R)$ is complete bipartite with vertex-sets $\{(0,1),(0, a)\}$ and $\{(1,0),(a, 0)\}$.

In the next theorem, we study the clique number of the graph $\Omega_{2}(R) \backslash I M(R)$ for a c-semilocal semiring. Also, with this theorem, we give a result about the girth of $\Omega_{2}(R) \backslash I M(R)$.
3.6 Theorem. Let $R$ be a $c$-semilocal semiring and $|C o-\operatorname{Max}(R)| \geq n$ with $n \geq 2$. Then $\Omega_{2}(R) \backslash I M(R)$ has a clique of order $n$. In particular, if $\mid C o-$ $\operatorname{Max}(R) \mid=n$, then $\omega\left(\Omega_{2}(R) \backslash I M(R)\right)=n$.
Proof: Let $\left\{m_{1}, \ldots, m_{n}\right\}$ be a subset of $C o-\operatorname{Max}(R)$. We claim that for any $x_{1} \in m_{1} \backslash \bigcup_{j=2}^{n} m_{j}$, there exists a clique with vertex-set $\left\{x_{1}, \ldots, x_{n}\right\}$ in $\Omega_{2}(R) \backslash I M(R)$, where $x_{i} \in m_{i} \backslash \bigcup_{\substack{j=1 \\ j \neq i}}^{n} m_{j}$ for $i=1, \ldots, n$. We prove this claim by induction on $n$. For $n=2$, the proof is similar to the proof of Theorem 3.4. Now, suppose that $n \geq 3$. By Remark 2.5, $m_{1} \cap m_{n} \nsubseteq \bigcup_{j=2}^{n-1} m_{j}$. Thus there exists $y \in\left(m_{1} \cap m_{n}\right) \backslash \bigcup_{j=2}^{n-1} m_{j}$ and so $x_{1}+y \in\left(m_{1} \cap m_{n}\right) \backslash \bigcup_{j=2}^{n-1} m_{j}$. By induction hypothesis, there is a clique with vertex-set $\left\{x_{1}+y, x_{2}, \ldots, x_{n-1}\right\}$, where $x_{i} \in m_{i} \backslash \bigcup_{j=1}^{n-1} m_{j}$ for $2 \leq i \leq n-1$. Indeed, $x_{2}, \ldots, x_{n-1} \notin m_{n}$ since $x_{1}+y \in m_{n}$. On the other hand, since $x_{1}+y$ is adjacent to $x_{2}, \ldots, x_{n-1}$, hence $x_{1}$ is adjacent to $x_{2}, \ldots, x_{n-1}$ because $F\left(x_{1}+y\right) \subseteq F\left(x_{1}\right)$. Now, since $x_{1}+\cdots+x_{n-1} \notin m_{n}$ ( $m_{n}$ is prime), so by Proposition 3.2, there exists $x_{n} \in m_{n}$ which is adjacent to $x_{1}+\cdots+x_{n-1}$. This implies that $x_{n}$ is adjacent to $x_{1}, \ldots, x_{n-1}$ and we can conclude $\left\{x_{1}, \ldots, x_{n}\right\}$ is a clique of order $n$ in $\Omega_{2}(R) \backslash I M(R)$.

Now, suppose that $|C o-\operatorname{Max}(R)|=n$. Thus we have $\omega\left(\Omega_{2}(R) \backslash I M(R)\right) \geq n$. If $\Omega_{2}(R) \backslash I M(R)$ has a clique of order $k$ in which $k \geq n$, then by the Pigeon Hole Principal, two elements of the clique should belong to one maximal co-ideal, which is a contradiction. Hence $\omega\left(\Omega_{2}(R) \backslash I M(R)\right)=n$.

Theorem 3.6 leads to the following corollary:
3.7 Corollary. Let $R$ be a $c$-semilocal semiring with $|C o-\operatorname{Max}(R)| \geq 3$. Then $\operatorname{gr}\left(\Omega_{2}(R) \backslash I M(R)\right)=3$.
Proof: Let $|C o-\operatorname{Max}(R)| \geq 3$. By Theorem 3.6, $\Omega_{2}(R) \backslash I M(R)$ has a clique of order 3 , so $g r\left(\Omega_{2}(R) \backslash I M(R)\right)=3$.

In the next theorem, we will compute the girth of $\Omega_{2}(R) \backslash I M(R)$ when $R$ is a c-semilocal semiring.
3.8 Theorem. Let $R$ be a c-semilocal semiring with $|C o-\operatorname{Max}(R)| \geq 2$. If $\Omega_{2}(R) \backslash I M(R)$ contains a cycle, then $\operatorname{gr}\left(\Omega_{2}(R) \backslash I M(R)\right) \leq 4$.

Proof: Assume that $\Omega_{2}(R) \backslash I M(R)$ contains a cycle and $\operatorname{gr}\left(\Omega_{2}(R) \backslash I M(R)\right) \neq$ 3. So Corollary 3.7 implies that $|\operatorname{Co}-\operatorname{Max}(R)|=2$. Hence by Theorem 3.4, $\Omega_{2}(R) \backslash I M(R)$ is complete bipartite graph and so $\operatorname{gr}\left(\Omega_{2}(R) \backslash I M(R)\right)=4$.
3.9 Example. Let $X=\{a, b, c\}$ and $R=(P(X), \cup, \cap)$ be a semiring, where $P(X)$ is the power set of $X$. For this semiring we have $1_{R}=X$ and $0_{R}=\emptyset$. In this case, the maximal co-ideals of semiring $R$ are as follows:

$$
\begin{aligned}
m_{1} & =\{\{a\},\{a, b\},\{a, c\}, X\}, \\
m_{2} & =\{\{b\},\{a, b\},\{b, c\}, X\}, \\
m_{3} & =\{\{c\},\{a, c\},\{b, c\}, X\} .
\end{aligned}
$$

For the graph $\Omega_{2}(R) \backslash I M(R)$ the vertex-set is $P(X) \backslash\{\emptyset, X\}$ and $\{\{\mathrm{a}\},\{\mathrm{b}\},\{\mathrm{c}\}\}$ is a maximal clique. This implies that $\omega\left(\Omega_{2}(R) \backslash I M(R)\right)=3$ and so $\operatorname{gr}\left(\Omega_{2}(R) \backslash\right.$ $I M(R))=3$.
3.10 Proposition. Let $R$ be a c-semilocal semiring with $|\operatorname{Co}-\operatorname{Max}(R)| \geq 2$. Then $\Omega_{2}(R) \backslash I M(R)$ is star graph if and only if there is a vertex of $\Omega_{2}(R) \backslash I M(R)$ which is adjacent to every other vertex.

Proof: The necessity is obvious by definition, thus we need to prove the sufficiency. Assume that there exists $x \in \Omega_{2}(R) \backslash I M(R)$ that is adjacent to every other vertex. Let $x \in m$ for some $m \in \operatorname{Co}-\operatorname{Max}(R)$. We must have $|m \backslash I M(R)|=1$, because if $x$ and $y$ are distinct vertices of $m \backslash I M(R)$, then by assumption $x$ and $y$ are adjacent, which is impossible. Now, if $|\operatorname{Co}-\operatorname{Max}(R)| \geq 3$, then $|m \backslash I M(R)| \geq 3$ for any maximal co-ideal $m$ of $R$. Hence $R$ cannot contain more than two maximal co-ideals. It is straightforward to verify that $\Omega_{2}(R) \backslash I M(R)$ is a star graph by Theorem 3.4.
3.11 Theorem. Let $R$ be a $c$-semilocal semiring with $|C o-\operatorname{Max}(R)| \geq 2$. Then the following statements are equivalent:
(1) $\Omega_{2}(R) \backslash I M(R)$ is a tree;
(2) $\Omega_{2}(R) \backslash I M(R)$ is a forest;
(3) $|\operatorname{Co}-\operatorname{Max}(R)|=2$ and $|m \backslash I M(R)|=1$ for some $m \in \operatorname{Co}-\operatorname{Max}(R)$;
(4) $\Omega_{2}(R) \backslash I M(R)$ is a star graph.

Proof: $(1) \Rightarrow(2),(3) \Rightarrow(4)$ and $(4) \Rightarrow(1)$ are clear.
$(2) \Rightarrow(3)$ Let $\Omega_{2}(R) \backslash I M(R)$ be a forest. Thus by Corollary 3.7, we have $|C o-\operatorname{Max}(R)|=2$. Now, if $|m \backslash I M(R)| \geq 2$ for each maximal co-ideal $m$, then $\Omega_{2}(R) \backslash I M(R)$ contains a cycle of order 4 , because by Theorem $3.4, \Omega_{2}(R) \backslash I M(R)$ is a complete bipartite graph, a contradiction. Hence $|m \backslash I M(R)|=1$ for some $m \in C o-\operatorname{Max}(R)$.
3.12 Proposition. Let $R$ be a c-semilocal semiring. Then $\Omega_{2}(R) \backslash I M(R)$ is a complete graph if and only if it is in the form $K_{1,1}$.
Proof: Let $\Omega_{2}(R) \backslash I M(R)$ be a complete graph. So we can say that there is a vertex of $\Omega_{2}(R) \backslash I M(R)$ that is adjacent to every other vertex. Hence by

Proposition 3.10, $\Omega_{2}(R) \backslash I M(R)$ is a star graph and Theorem 3.11 implies that $R$ has exactly two maximal co-ideals $m_{1}$ and $m_{2}$ so that $\left|m_{i} \backslash I M(R)\right|=1$ for some $i$. Now, since for each maximal co-ideal $m_{i}$, the vertex-set $m_{i} \backslash I M(R)$ is a partition of $\Omega_{2}(R) \backslash I M(R)$, we must have $\left|m_{i} \backslash I M(R)\right|=1$ for any $i$, because the elements of $m_{i} \backslash I M(R)$ are not adjacent to each other. In this case, $\Omega_{2}(R) \backslash I M(R)$ is in the form $K_{1,1}$.

The converse is obvious.
3.13 Example. Let $X=\{a, b\}$ and $R=(P(X), \cup, \cap)$ be a semiring, where $P(X)$ is power set of $X$ and $1_{R}=X$ and $0_{R}=\emptyset$. The maximal co-ideals of semiring $R$ are as follows:

$$
\begin{aligned}
m_{1} & =\{\{a\}, X\} \\
m_{2} & =\{\{b\}, X\}
\end{aligned}
$$

Thus by Theorem 3.4, $\Omega_{2}(R) \backslash I M(R)$ is a complete bipartite graph with vertexsets $V_{1}=\{\{a\}\}$ and $V_{2}=\{\{b\}\}$. Indeed, $\Omega_{2}(R) \backslash I M(R)$ forms $K_{1,1}$. Hence $\Omega_{2}(R) \backslash I M(R)$ is complete graph that is a star graph and a tree. Also, since $\Omega_{2}(R) \backslash I M(R)$ does not contain any cycle, so it is a forest and $\operatorname{gr}\left(\Omega_{2}(R) \backslash\right.$ $I M(R))=\infty$.
3.14 Theorem. Let $R$ be a c-semilocal semiring which is not a c-local. Then the following hold.
(i) If $|\operatorname{Co}-\operatorname{Max}(R)|=n$, then $\Omega_{2}(R) \backslash I M(R)$ is n-partite.
(ii) If $\Omega_{2}(R) \backslash I M(R)$ is $n$-partite, then $|C o-\operatorname{Max}(R)| \leq n$. In this case, if $\Omega_{2}(R) \backslash I M(R)$ is not $(n-1)$-partite, then $|C o-\operatorname{Max}(R)|=n$.

Proof: (i) Suppose that $C o-\operatorname{Max}(R)=\left\{m_{1}, \ldots, m_{n}\right\}$. Let $V_{1}=m_{1} \backslash I M(R)$ and $V_{i}=m_{i} \backslash \bigcup_{j=1}^{i-1} m_{j}$ for $2 \leq i \leq n$. By Remark $2.5, V_{i} \neq \emptyset$ for each $i$. Also, clearly that $\bigcup_{i=1}^{n} V_{i}=U M(R) \backslash I M(R)$ and for every $x, y \in V_{i}$, they are not adjacent in $\Omega_{2}(R) \backslash I M(R)$. Hence $\Omega_{2}(R) \backslash I M(R)$ is $n$-partite graph.
(ii) Assume contrary that $|C o-\operatorname{Max}(R)| \geq n+1$. By Theorem 3.6, $\Omega_{2}(R) \backslash$ $I M(R)$ has a clique with cardinality $n+1$. Thus by the Pigeon Hole Principal, two elements of this clique should belong to one part of $\Omega_{2}(R) \backslash I M(R)$, which is a contradiction.

Now, if $\Omega_{2}(R) \backslash I M(R)$ is not $(n-1)$-partite and $|C o-\operatorname{Max}(R)|=k<n$, then by part $(i), \Omega_{2}(R) \backslash I M(R)$ can be a $k$-partite graph, a contradiction.
3.15 Proposition. Let $R$ be a semiring with $|\operatorname{Co}-\operatorname{Max}(R)| \geq 2$. If $\Omega_{2}(R) \backslash$ $I M(R)$ is complete $n$-partite graph, then $n=2$.

Proof: Let $\left\{m_{1}, m_{2}\right\} \subseteq C o-\operatorname{Max}(R)$. By Proposition 3.2, it is clear that there exists at least one element of $m_{1} \backslash I M(R)$ which is adjacent to one element of $m_{2} \backslash I M(R)$. Also, $m_{i} \backslash I M(R)$ is totally disconnected for any $m_{i} \in \operatorname{Co}-\operatorname{Max}(R)$, so $m_{1} \backslash I M(R)$ and $m_{2} \backslash I M(R)$ are entirely contained in one of partitions of $\Omega_{2}(R) \backslash I M(R)$. This implies that $\left(m_{1} \backslash I M(R)\right) \cap\left(m_{2} \backslash I M(R)\right)=\emptyset$ and hence
$m_{1} \cap m_{2} \subseteq I M(R)$. Therefore we have $m_{1} \cap m_{2}=I M(R)$. Thus $|\operatorname{Co}-\operatorname{Max}(R)|=$ 2 and by Theorem 3.4, $\Omega_{2}(R) \backslash I M(R)$ is a complete bipartite graph.

As mentioned in the introduction, Beck conjectured that $\chi(R)=\omega(R)$ for every ring $R$. In the following theorem we want to establish Beck's conjecture for the graph $\Omega_{2}(R) \backslash I M(R)$ of c-semilocal semiring.

We recall that the chromatic number of the graph $G$, denoted by $\chi(G)$, is the minimal number of colors which can be assigned to the vertices of $G$ in such a way that any two adjacent vertices have different colors.
3.16 Theorem. Let $R$ be a c-semilocal semiring with $|\operatorname{Co}-\operatorname{Max}(R)|=n$. Then $\chi\left(\Omega_{2}(R) \backslash I M(R)\right)=\omega\left(\Omega_{2}(R) \backslash I M(R)\right)=n$.

Proof: Let $\operatorname{Co}-\operatorname{Max}(R)=\left\{m_{1}, \ldots, m_{n}\right\}$. By Theorem 3.6, we know that $\omega\left(\Omega_{2}(R) \backslash I M(R)\right)=n$. Also, it is obvious that $\chi(G) \geq \omega(G)$ for any graph $G$, so $\chi\left(\Omega_{2}(R) \backslash I M(R)\right) \geq n$. On the other hand, $\Omega_{2}(R) \backslash I M(R)$ is $n$-partite by Theorem 3.14, thus the elements of each part can be colored by an identical color because these elements are not adjacent. Hence $\chi\left(\Omega_{2}(R) \backslash I M(R)\right)=n$.

## 4. Diameter and radius of $\Omega(R)$

In this section, we show that $\Omega_{2}(R) \backslash I M(R)$ is a connected graph and $\operatorname{diam}\left(\Omega_{2}\right.$ $(R) \backslash I M(R)) \leq 3$. Also, we compute the eccentricity of the vertices of $\Omega_{2}(R) \backslash$ $I M(R)$.
4.1 Theorem. Let $R$ be a semiring. The graph $\Omega_{2}(R) \backslash I M(R)$ is connected with $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right) \leq 3$.

Proof: Let $x, y \in \Omega_{2}(R) \backslash I M(R)$ that are not adjacent. We consider two cases:
Case 1: Suppose that $x+y \notin I M(R)$. By Proposition 3.3, $F(x+y) F(a)=R$, for some $a \in \Omega_{2}(R) \backslash I M(R)$. This implies that $F(x) F(a)=F(y) F(a)=R$ since $F(x+y) \subseteq F(x), F(y)$. Hence $x-a-y$ is a path in $\Omega_{2}(R) \backslash I M(R)$ and $d(x, y)=2$.

Case 2: Suppose that $x+y \in I M(R)$. Thus for each $m \in \operatorname{Co}-\operatorname{Max}(R)$, we have $x \in m$ or $y \in m$. Since $x \notin I M(R)$, by Proposition 3.3, there exists $a \in \Omega_{2}(R) \backslash I M(R)$ such that $x$ is adjacent to $a$ in $\Omega_{2}(R) \backslash I M(R)$. Hence if $x \in m$ for maximal co-ideal $m$, then $a \notin m$. Now, there exists $n \in C o-\operatorname{Max}(R)$ in which $y \notin n$, since $y \notin I M(R)$. This implies that $x \in n$ and $a \notin n$. As $n$ is prime co-ideal, we have $a+y \notin I M(R)$. So by Case $1, d(a, y) \leq 2$ and hence $d(x, y) \leq 3$.

We recall that for a graph $G$, the eccentricity of a vertex $x$ is $e(x)=$ $\operatorname{Max}\{d(y, x) ; y \in V(G)\}$. A vertex $x$ with smallest eccentricity is called a center of $G$ and its eccentricity is called the radius of $G$ and is denoted by $\operatorname{rad}(G)$.
4.2 Proposition. Let $R$ be a c-semilocal semiring with $|\operatorname{Co}-\operatorname{Max}(R)| \geq 3$. If $x \in \Omega_{2}(R) \backslash I M(R)$ belongs to at least two maximal co-ideals, then $e(x)=3$.

Proof: Suppose that for $x \in \Omega_{2}(R) \backslash I M(R)$ there exist at least two maximal coideals $m_{i}$ and $m_{j}$ so that $x$ is contained in $m_{i} \cap m_{j}$. By Theorem 4.1, $d(x, y) \leq 3$ for any $y \in \Omega_{2}(R) \backslash I M(R)$. Now to complete the proof, it suffices to show that, there is an element $y$ in $\Omega_{2}(R) \backslash I M(R)$ such that $d(x, y)=3$. Let $y \in \bigcap_{\substack{k=1 \\ k \neq i}}^{n} m_{k} \backslash I M(R)$. Clearly that $d(x, y) \neq 1$, since $x, y \in m_{j}$. If $d(x, y)=2$, then $x-a-y$ is a path for some $a \in \Omega_{2}(R) \backslash I M(R)$. Now, as $x \in m_{i} \cap m_{j}$, thus $a \notin m_{i}, m_{j}$. Also, $y \in \bigcap_{\substack{k=1 \\ k \neq i}}^{n} m_{k} \backslash I M(R)$ implies that $a \notin m_{k}$, for $1 \leq k \leq n$ and $k \neq i$. Indeed, this implies that $a \notin m$ for any $m \in C o-\operatorname{Max}(R)$, that is impossible. So we can conclude that $d(x, y)=3$ and hence $e(x)=3$.
4.3 Corollary. Let $R$ be a $c$-semilocal semiring with $|C o-M a x(R)| \geq 3$. Then $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right)=3$.

Proof: We know that $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right) \leq 3$, by Theorem 4.1. On the other hand, $|C o-\operatorname{Max}(R)| \geq 3$ implies that there is an element $x$ in $\Omega_{2}(R) \backslash I M(R)$ that belongs to at least two maximal co-ideals. Now, the proof is immediate from Proposition 4.2.
4.4 Proposition. Let $R$ be a semiring with $|C o-\operatorname{Max}(R)|=2$. If $\left|m_{i}\right|$ $I M(R) \mid \geq 2$ for some $i$, then $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right)=2$.
Proof: Assume that $|C o-\operatorname{Max}(R)|=2$. By Theorem 3.4, $\Omega_{2}(R) \backslash I M(R)$ is complete bipartite graph and thus $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right) \leq 2$. On the other hand, $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right) \neq 1$ because $\left|m_{i} \backslash I M(R)\right| \geq 2$ for some $i$. Hence $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right)=2$.
4.5 Theorem. Let $R$ be a semiring. If $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right)=2$, then $R$ has an infinite number of maximal co-ideals or $|\operatorname{Co}-\operatorname{Max}(R)|=2$ such that $\left|m_{i} \backslash I M(R)\right| \geq 2$ for some $i=1,2$.
Proof: Assume that $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right)=2$ and $|C o-M a x(R)|$ is finite. If $n \geq 3$, then by Corollary 4.3, $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right)=3$, which is a contradiction. Thus we must have $|C o-\operatorname{Max}(R)|=2$. Now, if $\left|m_{i} \backslash I M(R)\right|=1$ for each $i$, then $\operatorname{diam}\left(\Omega_{2}(R) \backslash I M(R)\right)=1$ because $\Omega_{2}(R) \backslash I M(R)$ is a complete bipartite graph, this is a contradiction. Hence $\left|m_{i} \backslash I M(R)\right| \geq 2$ for some $i$.
4.6 Theorem. Let $R$ be a c-semilocal semiring with $|\operatorname{Co}-\operatorname{Max}(R)|=n \geq 2$. If $\Omega_{2}(R) \backslash I M(R)$ is not a star graph, then we have:

$$
e(x)= \begin{cases}2 & \text { if } x \in m_{i} \backslash \bigcup_{\substack{j=1 \\ j \neq i}}^{n} m_{j} \\ 3 & \text { otherwise }\end{cases}
$$

Proof: First, we claim that for any $a \in \Omega_{2}(R) \backslash I M(R), e(a) \neq 1$. Suppose that there is an element $x$ of $\Omega_{2}(R) \backslash I M(R)$ such that $e(x)=1$. This means that $x$ is adjacent to any vertex of $\Omega_{2}(R) \backslash I M(R)$ and so $\Omega_{2}(R) \backslash I M(R)$ is a star graph by Proposition 3.10, which is a contradiction. Now, suppose that $x \in m_{i} \backslash \bigcup_{\substack{j=1 \\ j \neq i}}^{n} m_{j}$.

For any $y \in \bigcup_{\substack{j=1 \\ j \neq i}}^{n} m_{j} \backslash m_{i}$, if $F(x) F(y) \neq R$, then $F(x) F(y) \subseteq m_{k}$ for some $m_{k} \in \operatorname{Co}-\operatorname{Max}(R)$. Hence $x, y \in m_{k}$, that is a contradiction. Therefore, in this case $d(x, y)=1$. But, if $y \in m_{i} \backslash I M(R)$ and $y \neq x$, then by proof of Theorem 4.1, $d(x, y) \leq 2$ since $x+y \notin I M(R)$. Clearly $x$ and $y$ are not adjacent and so $d(x, y)=2$. According to the assumption, since $\Omega_{2}(R) \backslash I M(R)$ is not star graph thus by Theorem $3.11((4) \Rightarrow(3))|C o-\operatorname{Max}(R)| \geq 2$ and $|m \backslash I M(R)| \geq 2$ for each $m \in C o-\operatorname{Max}(R)$. Hence $e(x)=2$ for any $x \in m_{i} \backslash \bigcup_{j=1}^{n} m_{j}$.

Now, suppose that $x \notin m_{i} \backslash \underset{\substack{j=1 \\ j \neq i}}{n} m_{j}$ for any maximal co-ideal $m_{i}$. Hence there are at least two maximal co-ideals $m_{k}$ and $m_{j}$ so that $x$ is contained in $m_{k} \cap m_{j}$. This implies that $|\operatorname{Co}-\operatorname{Max}(R)| \geq 3$, thus by Proposition 4.2 we have $e(x)=3$.
4.7 Corollary. Let $R$ be a $c$-semilocal semiring with $|\operatorname{Co}-\operatorname{Max}(R)|=n \geq 2$. If $\Omega_{2}(R) \backslash I M(R)$ is not a star graph, then the elements of $m_{i} \backslash \bigcup_{\substack{j=1 \\ j \neq i}}^{n} m_{j}$ are center of $\Omega_{2}(R) \backslash I M(R)$ for each $m_{i} \in C o-\operatorname{Max}(R)$ and $\operatorname{rad}\left(\Omega_{2}(R) \backslash I M(R)\right)=2$.

Proof: This is an immediate consequence of Theorem 4.6.
4.8 Proposition. Let $R$ be a semiring with $|C o-\operatorname{Max}(R)|=2$. Then $\operatorname{rad}\left(\Omega_{2}(R) \backslash I M(R)\right)=1$ or 2 .

Proof: We know by Theorem 3.4, $\Omega_{2}(R) \backslash I M(R)$ is a complete bipartite graph when $|C o-\operatorname{Max}(R)|=2$. Now, if $\Omega_{2}(R) \backslash I M(R)$ is a star graph, clearly $\operatorname{rad}\left(\Omega_{2}(R) \backslash I M(R)\right)=1$. Otherwise, $\operatorname{rad}\left(\Omega_{2}(R) \backslash I M(R)\right)=2$ and all elements of $\Omega_{2}(R) \backslash I M(R)$ are center.

## 5. The relations between $\Omega(R)$ and $\Gamma(R)$

In this section, we will investigate the relations between the zero-divisor graph $\Gamma(R)$ and $\Omega(R)$. We show that $\Gamma(R)$ is a subgraph of the $\Omega(R)$. Also, we determine a family of commutative semirings whose zero-divisor graph $\Gamma(R)$ and $\Omega_{2}(R)$ are isomorphic.

We recall that an isomorphism from a simple graph $G$ to a simple graph $H$ is a bijection $f: V(G) \rightarrow V(H)$ such that $x$ and $y$ are adjacent in $G$ if and only if $f(x)$ and $f(y)$ are adjacent in $H$. We say $G$ is isomorphic to $H$, if there is an isomorphism from $G$ to $H$, denoted by $G \cong H$.
5.1 Theorem. The zero-divisor graph $\Gamma(R)$ is a subgraph of the graph $\Omega(R)$.

Proof: Suppose that $x$ and $y$ are two distinct adjacent vertices in $\Gamma(R)$. Thus $x y=0$ and this implies $F(x) F(y)=R$, since $0=x y \in F(x) F(y)$. Hence $x$ and $y$ are adjacent in $\Omega(R)$. Now, since the vertex-set of zero-divisor graph is $Z(R)^{*}$, thus we can conclude that $\Gamma(R)$ is a subgraph of $\Omega(R)$.
5.2 Theorem. Let $R$ be a multiplicatively idempotent and zero-sumfree semiring. Then the zero-divisor graph $\Gamma(R)$ is an induced subgraph of the graph $\Omega(R)$.

Proof: By Theorem 5.1, $\Gamma(R)$ is a subgraph of $\Omega(R)$. Thus it is enough to show that if $x, y \in Z(R)^{*}$ and they are adjacent in $\Omega(R)$, then $x$ and $y$ are adjacent in $\Gamma(R)$. Assume that $x, y \in Z(R)^{*}$ and $F(x) F(y)=R$. So we have $\left(x^{n}+r\right)\left(y^{m}+s\right)+k=0$ for some positive integers $n, m$ and $r, s, k \in R$. Since $R$ is a multiplicatively idempotent, then we have $x y+a=0$ for some $a \in R$. Hence $x y=0$ because $R$ is a zero-sumfree semiring. This implies $x$ and $y$ are adjacent in $\Gamma(R)$.

Note that if $U M(R)=Z(R)^{*}$, then $\Gamma(R)$ is a spanning subgraph of $\Omega_{2}(R)$ by Theorem 5.1. Thus, if $R$ is a multiplicatively idempotent and zero-sumfree semiring, then we have the following result:
5.3 Corollary. Let $R$ be a multiplicatively idempotent and zero-sumfree semiring. If $Z(R)^{*}=U M(R)$, then the zero-divisor graph $\Gamma(R)$ and $\Omega_{2}(R)$ are isomorphic. In particular, if $Z(R)^{*}=U M(R) \backslash I M(R)$, then $\Gamma(R)$ and $\Omega_{2}(R) \backslash I M(R)$ are isomorphic.

Proof: This is an immediate consequence of Theorems 5.1 and 5.2.
To this end, we give an example that clarifies the previous results:
5.4 Example. Let $S=\{0,1, a\}$ and $R=(S \times S,+, \cdot)$ be a semiring as defined in Example 3.5. We know that $R$ is a multiplicatively idempotent. For this semiring, the vertex-set of $\Gamma(R)$ is

$$
Z(R)^{*}=\{(0,1),(1,0),(0, a),(a, 0)\}
$$

and the vertex-set of $\Omega_{2}(R)$ is $U M(R)=R \backslash\{(0,0)\}$. Clearly $\Gamma(R)$ is an induced subgraph of $\Omega(R)$ and $\Omega_{2}(R)$. On the other hand, $(0,0)$ is only zero-sum of $R$, thus $R$ is zero-sumfree semiring. We see that $U M(R) \backslash I M(R)=Z(R)^{*}$, so we can conclude that $\Gamma(R)$ and $\Omega_{2}(R) \backslash I M(R)$ are isomorphic by Corollary 5.3.
