SUMS OF TWO INTEGER SQUARES
IN A CERTAIN QUARTIC EXTENSION

ALBERTAS ZINEVIČIUS

ABSTRACT. An example of a quartic extension of the rational number field that does not have quadratic subfields and there exists a set of rational prime numbers $p \equiv 3 \pmod{4}$ of positive Dirichlet density such that either p or $31p$ is a sum of two squares of integers of the extension is given.

1. INTRODUCTION

In [11] it was proved that, given a number field K , there is a set of rational prime numbers of positive Dirichlet density that are not sums of two cubes of integers of K . In comparison, every rational integer is a sum of two squares of Gaussian integers (sums of two integer squares in quadratic extensions have been studied, for example, in [7] and [9]). In fact if $K = \mathbb{Q}(\sqrt{-D})$ (where D is a square-free positive integer) is any other imaginary quadratic extension there exists a nonzero constant a such that the set of rational prime numbers $p \equiv 3 \pmod{4}$ for which ap is a sum of two squares of integers of K has positive upper Dirichlet density. Indeed consider the Galois group $\text{Gal}(H(K(i))/\mathbb{Q})$ of the Hilbert class field $H(K(i))$ of $K(i)$. If the Frobenius automorphism of some prime ideal in $H(K(i))$ above the rational prime ideal (p) is in the division of the complex conjugation automorphism then (p) is inert in extensions $K, \mathbb{Q}(i)$ and has a principal prime ideal factor $(x + yi)$ of degree 2 in $K(i)$ where $2x, 2y$ are some integers of K . Therefore the ideal (p) is equal to $(x^2 + y^2)$ and since the only roots of unity in K are ± 1 (or the sixth roots of unity in the case $D = 3$), either $4p$ or $4Dp$ is a sum of two integer squares. It is therefore interesting to find an example of an extension K that has the aforementioned property and does not contain any quadratic subfield.

Theorem 1.1. *The quartic extension generated by a root of the polynomial $x^4 - 3x^3 + 3x^2 + 2x + 1$ does not have quadratic subfields. There exists a set of rational prime numbers $p \equiv 3 \pmod{4}$ of positive Dirichlet density such that either p or $31p$ is a sum of two squares of integers of the extension.*

Notice that a related question was discussed in [1].

The following theorems will be used in the proof:

Lemma 1.2 (Existence of Hilbert class field). [2, p. 153] *If K is a number field, there exists a unique abelian extension $H(K)$ of K with the Galois group isomorphic to the class group of K such that no prime ideal $\mathfrak{p} \subset \mathcal{O}_K$ ramifies in $H(K)/K$ and no injective ring homomorphism $\sigma: K \rightarrow \mathbb{R}$ extends to an injective ring homomorphism $\sigma: H(K) \rightarrow \mathbb{C}$ with $\sigma(H(K)) \not\subset \mathbb{R}$. It has the property that a prime ideal $\mathfrak{p} \subset \mathcal{O}_K$ splits completely in $H(K)/K$ if and only if it is principal.*

Definition 1.3. If G is a finite group and $\sigma \in G$, the *division* of σ is the set of all elements of G that are conjugate to σ^m for some $m \in \mathbb{N}$ that is coprime to the order of σ .

Lemma 1.4 (Frobenius density theorem). [3, p. 134] *If L/K is a Galois extension of number fields and $\sigma \in \text{Gal}(L/K)$, the Dirichlet density of the set of prime ideals of \mathcal{O}_K that are divisible by a prime ideal of \mathcal{O}_L such that its Frobenius automorphism is in the division of σ , is equal to the number of elements in the division of σ divided by the number of elements of $\text{Gal}(L/K)$.*

Lemma 1.5. [3, p. 101] *If $K \subset L \subset M$ are number fields such that M/K is Galois, the decomposition type of a prime ideal $\mathfrak{p} \subset \mathcal{O}_K$ in L that is not ramified in M/K is the same as the cycle structure of the permutation of (left) cosets of $\text{Gal}(M/K) \setminus \text{Gal}(M/L)$ induced by the Frobenius automorphism of any prime ideal $\mathfrak{q} \subset \mathcal{O}_M$ above \mathfrak{p} .*

Lemma 1.6. [8, p. 202] *If $K \subset L \subset M$ are number fields, then the discriminant ideals are related by*

$$\mathfrak{d}_{M/K} = \mathfrak{d}_{L/K}^{[M:L]} \text{Nm}_{L/K} \mathfrak{d}_{M/L}.$$

Lemma 1.7. [8, p. 202] *A prime ideal $\mathfrak{p} \subset \mathcal{O}_K$ ramifies in the extension L/K of number fields if and only if it divides the discriminant ideal $\mathfrak{d}_{L/K}$.*

Lemma 1.8. [6, p. 68] *A prime ideal $\mathfrak{p} \subset \mathcal{O}_K$ divides the discriminant ideal $\mathfrak{d}_{L/K}$ if and only if it divides the discriminant ideal of the Galois closure of L over K .*

2. AUXILIARY CALCULATIONS

Denote $f(x) = x^4 - 3x^3 + 3x^2 + 2x + 1 \in \mathbb{Q}[x]$. Notice that

$$f(x) \equiv (x-1)(x^3+x+1) \pmod{2},$$

$$(2.1) \quad f(x) \equiv (x^2+x+1)^2 \pmod{5}.$$

Therefore $f(x)$ is irreducible. The discriminant of f is $\text{disc}(f) = 5^2 13^2$. Denote by u a root of $f(x)$ and denote by K the field extension $\mathbb{Q}(u)$.

Notice that u is a unit. Further, $(u^2 + u + 1)^2 = 5u^3$, therefore the ideal (5) ramifies in the ring of integers \mathcal{O}_K . It follows that 5^2 divides the discriminant $d_{K/\mathbb{Q}}$ of the extension K/\mathbb{Q} . 13^2 must also divide $d_{K/\mathbb{Q}}$ since otherwise [4, p. 63] Minkowski bound would be less than 1. Therefore $\text{disc}(f) = d_{K/\mathbb{Q}}$. Consequently, $1, u, u^2, u^3$ is a basis of \mathcal{O}_K as a \mathbb{Z} -module.

Since 2 does not divide $\text{disc}(f)$, it follows from [4, p. 55] that the ideal (2) factorizes as $(2, u - 1)(2, u^3 + u + 1)$ in \mathcal{O}_K . Therefore the extension K/\mathbb{Q} is not Galois and the degree of its Galois closure is divisible by 3. On the other hand, $\text{disc}(f)$ is a square, therefore the Galois group of f must be a subgroup of the alternating group A_4 [5, p. 47]. Consequently, it must be A_4 . Therefore K does not have nontrivial subfields. In particular, the only roots of unity in K are ± 1 . Since the polynomial f does not have real roots, the unit group of \mathcal{O}_K has rank 1, as follows from the Dirichlet unit theorem.

Lemma 2.1. *$u, -u$ are not squares in \mathcal{O}_K .*

Proof. If $u = \beta^2$ for some $\beta \in \mathcal{O}_K$, then $f(\beta^2) = 0$. Therefore $f(x^2)$ must be divisible by the minimal polynomial of β of degree 4. However

$$f(x^2) \equiv (x^6 - x^4 + x^2 + 1)(x^2 + 1) \pmod{3}$$

and the polynomial $x^6 - x^4 + x^2 + 1 \in \mathbb{F}_3[x]$ is irreducible. Contradiction. Therefore u is not a square in \mathcal{O}_K .

If $-u = \beta^2$ for some $\beta \in \mathcal{O}_K$, then $f(-\beta^2) = 0$. Therefore $f(-x^2)$ must be divisible by the minimal polynomial of β of degree 4. However

$$f(-x^2) \equiv (x^6 - x^4 - 4x^2 + 3)(x^2 + 4) \pmod{11}$$

and the polynomial $x^6 - x^4 - 4x^2 + 3 \in \mathbb{F}_{11}[x]$ is irreducible. Contradiction. Therefore $-u$ is not a square in \mathcal{O}_K . \square

Lemma 2.2. *The ring of integers of $K(i)$ is $\mathcal{O}_K[i]$.*

Proof. $\mathfrak{d}_{K(i)/K}$ divides $(d_{K(i)/K}(1, i)) = (-4)$. Therefore from lemma 1.6,

$$\mathfrak{d}_{K(i)/\mathbb{Q}} = \mathfrak{d}_{K/\mathbb{Q}}^{[K(i):K]} \text{Nm}_{K/\mathbb{Q}} \mathfrak{d}_{K(i)/K} = (5^4 13^4 2^e)$$

for some nonnegative integer $e \leq 8$. On the other hand,

$$\mathfrak{d}_{K(i)/\mathbb{Q}} = \mathfrak{d}_{\mathbb{Q}(i)/\mathbb{Q}}^{[K(i):\mathbb{Q}(i)]} \text{Nm}_{\mathbb{Q}(i)/\mathbb{Q}} \mathfrak{d}_{K(i)/\mathbb{Q}(i)} = (-4)^4 \text{Nm}_{\mathbb{Q}(i)/\mathbb{Q}} \mathfrak{d}_{K(i)/\mathbb{Q}(i)}.$$

Therefore $e = 8$. Since $5^4 13^4 2^8 = d_{K(i)/\mathbb{Q}}(1, u, u^2, u^3, i, ui, u^2i, u^3i)$, the ring of integers of $K(i)$ must be $\mathbb{Z} + \mathbb{Z}u + \mathbb{Z}u^2 + \mathbb{Z}u^3 + \mathbb{Z}i + \mathbb{Z}ui + \mathbb{Z}u^2i + \mathbb{Z}u^3i = \mathcal{O}_K[i]$. \square

3. PROOF OF THE THEOREM

From lemma 1.7 it follows that the prime ideal $(31) \subset \mathbb{Z}$ does not ramify in the Hilbert class field $H(K(i))$ of $K(i)$. From lemma 1.8, the ideal (31) does not ramify in the Galois closure M (with respect to the base field \mathbb{Q}) of $H(K(i))$.

The polynomial $f(x)$ has no root modulo 31. On the other hand,

$$(3.1) \quad -31u = (2u^2 - 6u - 3)(2u^3 - 6u^2 + 9u + 4)$$

and $\text{Nm}_{K/\mathbb{Q}}(2u^2 - 6u - 3) = 31^2$. Consequently the ideals $\mathfrak{p}_1 = (2u^2 - 6u - 3)$, $\mathfrak{p}_2 = (2u^3 - 6u^2 + 9u + 4)$ are prime, of degree 2. Since

$$(3.2) \quad 2u^3 - 6u^2 + 9u + 4 = (u^3 - 3u^2 + 2u + 2)^2 + 1^2,$$

$$(3.3) \quad 2u^3 - 6u^2 - 3u = (2u^2 - 1)^2 + (u^3 - u^2 - 2u)^2,$$

the prime ideals $\mathfrak{p}_1, \mathfrak{p}_2$ split completely into a product of principal ideals in the extension $K(i)/K$. From lemma 1.2 it follows that the factors split completely in the extension $H(K(i))/K(i)$. Therefore (31) splits into a product of ideals of degree 2 in $H(K(i))$.

Denote by \mathfrak{q} any prime factor of (31) in \mathcal{O}_M and denote by $\sigma \in \text{Gal}(M/\mathbb{Q})$ the Frobenius automorphism of \mathfrak{q} . It follows from lemma 1.5 that the permutation of $\text{Gal}(M/\mathbb{Q}) \setminus \text{Gal}(M/L)$ induced by σ is a product of disjoint 2-cycles when L is $\mathbb{Q}(i), K, K(i), H(K(i))$. Since the restriction of σ to $\mathbb{Q}(i)$ is the Frobenius automorphism of $\mathfrak{q} \cap \mathcal{O}_{\mathbb{Q}(i)}$, and since (31) is inert in $\mathbb{Q}(i)$, the order of $\sigma|_{\mathbb{Q}(i)}$ is 2. Therefore the order of σ in $\text{Gal}(M/\mathbb{Q})$ is even. Denote by m any positive integer that is coprime to the order of σ . Then m is odd.

If $\tau \text{Gal}(M/L), \sigma\tau \text{Gal}(M/L)$ is a 2-cycle induced by σ , then $\sigma^2\tau \text{Gal}(M/L) = \tau \text{Gal}(M/L)$. Consequently, $\sigma^m\tau \text{Gal}(M/L) = \sigma\tau \text{Gal}(M/L)$ and $(\sigma^m)^2\tau \text{Gal}(M/L) = \tau \text{Gal}(M/L)$. Therefore the permutation of $\text{Gal}(M/\mathbb{Q}) \setminus \text{Gal}(M/L)$ induced by σ^m is the product of the same disjoint 2-cycles as is the permutation induced by σ . Therefore any prime ideal $(p) \subset \mathbb{Z}$ (generated by a prime number $p > 0$) that is not ramified in M/\mathbb{Q} and has a prime ideal factor in \mathcal{O}_M with Frobenius automorphism σ^m is a product of prime ideals of degree 2 in $\mathcal{O}_{\mathbb{Q}(i)}, \mathcal{O}_K, \mathcal{O}_{K(i)}, \mathcal{O}_{H(K(i))}$. If (p) has a prime ideal factor with Frobenius automorphism conjugate to σ^m , then it also has a prime ideal factor with Frobenius automorphism σ^m [4, p. 134]. Therefore every prime ideal $(p) \subset \mathbb{Z}$ that is not ramified in M/\mathbb{Q} and has a prime ideal factor with Frobenius automorphism in the division of σ is a product of prime ideals of degree 2 in $\mathcal{O}_{\mathbb{Q}(i)}, \mathcal{O}_K, \mathcal{O}_{K(i)}, \mathcal{O}_{H(K(i))}$. In particular, (p) is inert in $\mathbb{Q}(i)/\mathbb{Q}$, therefore $p \equiv 3 \pmod{4}$. It follows from lemma 1.4 that the Dirichlet density of such (p) is positive. The prime ideal factors of (p) in $K(i)$ split completely in the extension $H(K(i))/K(i)$ and therefore must be principal ideals. Moreover, they form two pairs of ideals that are conjugate by an element of $\text{Gal}(K(i)/K)$. By lemma 2.2, the ideals of such pair are of the form $(\beta_1 + i\beta_2), (\beta_1 - i\beta_2)$ for some $\beta_1, \beta_2 \in \mathcal{O}_K$. Therefore the prime ideals of \mathcal{O}_K above (p) are of the form $(\beta_1^2 + \beta_2^2)$. Since the product of sums of two squares is a sum of two squares, we must have

$$p = \epsilon(\alpha_1^2 + \alpha_2^2)$$

for some $\alpha_1, \alpha_2 \in \mathcal{O}_K$ and $\epsilon \in \mathcal{O}_K^\times$. Since the unit group of \mathcal{O}_K has rank 1 and the only roots of unity in K are ± 1 , there exists a unit $u_0 \in \mathcal{O}_K$ such that every unit is of the form $\pm u_0^l$ for some integer l . From lemma 2.1,

$$u = \pm u_0^l$$

for some odd integer l . Since

$$(2u)^2 + (1 + u - u^2)^2 = u^3,$$

u is a sum of two squares. Therefore either u_0 or $-u_0$ is a sum of two squares. Consequently either p or $-p$ is a sum of two squares in \mathcal{O}_K .

It follows from equations 3.1, 3.2, 3.3 that $-31u$ is a sum of two squares and therefore -31 is a sum of two squares. Therefore if p is not a sum of two squares then $-p \cdot (-31)$ is.

Acknowledgements. We used computer to generate the example. In particular, we are thankful to SageMath [10] for some of the computations. We are also thankful to the anonymous referee for their remarks and the short proof of lemma 2.1.
