A GENERAL TOPOLOGY APPROACH TO THE STUDY OF DIFFERENTIABILITY OF CONVEX FUNCTIONS IN BANACH SPACES

by P.Kenderov (Sofia)

(An abstract from a report presented at the 6-th Winter School on Abstract Analysis, Czechoslovakia 1978)

Let $E$ be a Banach space and $f : E \to \mathbb{R}$ be a real valued convex and continuous function whose domain $D(f) = \{ x \in E : f(x) < +\infty \}$ has interior points: int$D(f) \neq \emptyset$. $f$ is said to be Gâteaux differentiable at some point $x_0$ in int$D(f)$ if there exists $x^* \in E^*$ (:= the space of all linear continuous functionals in $E$) such that

$$\lim_{t \to 0} \frac{f(x_0 + th) - f(x_0)}{t} = x^*(h)$$

for every $h \in E$. $f$ is said to be Fréchet differentiable at $x_0$ if the above limit is uniform with respect to all $h$, $\|h\| \leq 1$. It is known that both Gâteaux and Fréchet differentiability of $f$ at $x_0$ can be easily expressed by means of the so called subgradient $\partial$ of $f$ (the latter is a multivalued mapping $\partial : E \to E^*$ assigning to each $x_0$ from $E$ the set $\partial(x_0) = \{ x^* \in E : \langle x - x_0, x^* \rangle \leq f(x) - f(x_0) \text{ for every } x \in E \}$).

**Proposition.** i) $f$ is Gâteaux differentiable at $x_0$ iff the set $\partial(x_0)$ is a singleton (i.e. consists of only one element).

ii) $f$ is Fréchet differentiable at $x_0$ iff $\partial(x_0)$ is a singleton and for every $\varepsilon > 0$ there exists $\delta > 0$ such that $\|x - x_0\| < \delta$ implies $\partial(x) \subset B(\partial(x_0), \varepsilon)$. Here $B(\cdot, \varepsilon)$ denotes the ball with center at $\cdot$ and of radius $\varepsilon$.

Therefore, if we want to prove that a given convex function \( f : E \rightarrow R \) is Gâteaux differentiable at the points of some dense \( G_δ \) subset of \( E \), it is enough to prove somehow that the multivalued mapping \( \partial : E \rightarrow E^* \) is single-valued at the points of such a subset of \( E \). In order to have Fréchet differentiability on dense \( G_δ \) subset of \( E \), it is enough to prove, in addition to the Gâteaux case, that \( \partial : E \rightarrow E^* \) satisfies the condition in ii) for every point from some dense \( G_δ \) subset of \( E \).

Now we would like to outline how a general topology phenomenon (concerning multivalued mappings) could be applied to the present situation so as to prove some known results about differentiability "almost everywhere" of convex functions defined in Banach spaces. Recall first that the multivalued mapping \( F : X \rightarrow Y \) from the topological space \( X \) into the topological space \( Y \) is said to be upper semicontinuous (lower semicontinuous) at \( x_0 \in X \) if for every open \( U \subset Y \), \( U \supseteq F(x_0) \) (\( U \cap F(x_0) \neq \emptyset \)) there exists an open \( V \) in \( X \), \( V \ni x_0 \), such that from \( x \in V \) it follows that \( F(x) \subseteq U \) (\( F(x) \cap U \neq \emptyset \)). One aspect of the general topology phenomenon we have in mind is expressed by the following theorem of Kuratowski ([4], p. 79) - Fort [2].

If \( F : X \rightarrow Y \) is an usc (lsc) multivalued mapping with compact images, acting from the topological space \( X \) into the metrizable space \( Y \), then \( F \) has to be lsc (usc) at the points of some dense \( G_δ \) subset of \( X \).

**Theorem (Moreau [6]).** If \( f : E \rightarrow R \) is a continuous con-

We will write for brevity "usc" (lsc) instead of "upper semicontinuous" (lower semicontinuous).
vex function, then \( \partial : E \rightarrow E^* \) is usc with respect to the
norm topology in \( E \) and weak* topology in \( E^* \) (i.e. \( \partial : (E, \| \|) \rightarrow (E^*, w^*) \) is usc) at every point of \( \text{int}D(f) \). Moreover, for every \( x_0 \) in \( \text{int}D(f) \) there exists an open \( V \ni x_0 \) such that \( \partial(V) = \bigcup_{x \in V} \partial(x) \) is a bounded subset of \( E^* \).

This theorem combined with the above mentioned theorem of Kuratowski-Fort implies the following corollary:

COROLLARY. If \( E \) is a separable Banach space and \( f : E \rightarrow R \) is continuous convex function, then \( \partial : (E, \| \|) \rightarrow (E^*, w^*) \) is lsc at the points of some dense \( G_\delta \) subset of \( \text{int}D(f) \).

The last (but decisive) step now is contained in the next

PROPOSITION (Kenderov [3], Robert [7]). If \( \partial : (E, \| \|) \rightarrow (E^*, w^*) \) is lsc at the point \( x_0 \in X \), then \( \partial(x_0) \) is a singleton (and therefore \( f : E \rightarrow R \) is Gâteaux differentiable at \( x_0 \)).

As a corollary we get the classical result of Mazur [5] that every continuous convex function defined in the separable Banach space \( E \) must be Gâteaux differentiable at the points of some dense \( G_\delta \) subset of \( E \).

Since all the argument above depends in fact only on
the monotonicity properties of \( \partial : E \rightarrow E^* \), we can apply
(in exactly the same way) the same general topology approach
in order to prove the result of Zarantonello [10] that every
multivalued monotone operator \( T : E \rightarrow E^* \) acting in the
separable Banach space \( E \) must be single-valued at the points of some dense \( G_\delta \) subset of \( \text{int}D(T) \), where \( D(T) = \{ x \in E : T(x) \neq \emptyset \} \). Taking as a start point another expression of
the same general topology phenomenon and applying it (in a
similar way) to more general situations, we can get some new results as well as new proofs of some known results concerning differentiability "almost everywhere" of convex functions (Asplund [1]), concerning single-valuedness "almost everywhere" of multivalued monotone operators and concerning uniqueness "almost everywhere" of the best approximations in Banach spaces (Stechkin [9]).
