The Fréchet space ω admits a strictly stronger separable and quasicomplete locally convex topology

Susanne Dierolf

<u>Definition</u>. A locally convex space is called submetrizable if it admits a coarser metrizable locally convex topology. <u>Lemma 1.</u> If X is a Hausdorff locally convex space and YCX a linear subspace such that dim (X/Y) is at most countable and such that Y is submetrizable, then also X is submetrizable.

Lemma 2. Let X be a locally convex space. Then X is separable if and only if the weak dual $(X, \sigma(X, X'))$ is submetrizable. <u>Proposition.</u> Let $\omega := \mathbf{C}^{\mathbb{N}}$ be provided with its product topology \mathcal{P} and let \mathcal{T} be any separable locally convex topology on ω . Then the supremum $\mathcal{P} \lor \mathcal{T}$ is also separable. <u>Example.</u> By an example of I. Amemyia - Y. Komura (Math.Ann. <u>177</u> (1968)) and R. Knowles - T. Cook (Proc.Camb.Phil.Soc. <u>74</u>(1973)) there exists a locally convex topology \mathcal{T} on ω such that (ω, \mathcal{T}) is separable and such that every bounded set in (ω, \mathcal{T}) has finite dimensional linear span. Now the supremum $\mathcal{T} \lor \mathcal{P}$ is separable, and every bounded set in $(\omega, \mathcal{T} \lor \mathcal{P})$ has finite dimensional linear span. Thus $\mathcal{T} \lor \mathcal{P}$ is quasicomplete and strictly stronger than \mathcal{T} .

This example answers a question by E. Thomas.
