ON THE RANGE OF NONLINEAR OPERATORS WITH LINEAR ASYMPTOTES WHICH ARE NOT INVERTIBLE

Djairo Guedes de FIGUEIREDO, Brasília

<u>Abstract</u>: Let $A: \mathbb{H} \to \mathbb{H}$ be a bounded linear self-adjoint operator in a real Hilbert space \mathbb{H} , with a closed range and a finite dimensional null-space. Assume that there exists a sequence $(\mathcal{A}_{\mathcal{M}})$ of positive real numbers in the resolvent set of A, such that $\mathcal{A}_{\mathcal{M}} \to 0$. Let $N: \mathbb{H} \to \mathbb{H}$ be a compact mapping which is not necessarily bounded, but it could have some sublinear growth for $\|\mathcal{A}\| \to \infty$, see inequality (5). Also assume some asymptotic condition on N with respect to the null-space of A, see condition (C). Under these hypotheses it is shown that the equation $A\mathcal{U} + N\mathcal{U} = \mathcal{H}$ has a solution; this theorem is applied to prove some results on the existence of solution for the nonlinear Dirichlet problem.

Key words: Dirichlet Problem for nonlinear elliptic equations. Compact operators, completely continuous operators. Mappings of type (M), coerciveness, perturbations of bounded linear self-adjoint operators.

AMS: 35J60, 47F05, 47H15 Ref. Z. 7.978.5

§ 1. <u>Introduction</u>. Recently Nečas [1] published a paper with a title like the one above, where he proved the following result.

<u>Theorem</u>. "Let H be a real Hilbert space, A: $H \rightarrow H$ a linear bounded self-adjoint operator, with a closed range and a finite dimensional nullspace N(A). Let $N: H \rightarrow H$ be a compact (on general nonlinear) mapping such that

 $\|\mathbf{N}\boldsymbol{u}\| \leq \mathbf{X}$

- 415 -

for all $\omega \in H$, and a fixed constant K > 0. Assume that, for each $w \in N(A)$, ||ww|| = 1, the limit

(2)
$$l(w) = \lim_{t \to \infty} (w, N(u+tw))$$

exists uniformly with respect to bounded sets of u. Finally suppose that, for each $w \in N(A)$, ||w|| = 1, we have

$$(3) \qquad (nr,h) < \mathcal{L}(nr),$$

where $h \in H$ is given. Then the equation

$$(4.) \qquad Au + Nu = h$$

has a solution $\mu \in \mathbb{H}$."

An extension of this result was obtained by Fučík, Kučera and Nečas [2], when they relaxed (1) and (2). In this note we propose to extend these results and also present a simpler technique to proving this type of results. The main idea of the proof is a sort of perturbation argument used in similar situations by the author [3], Hess [4], and surely others. Like 2 we shall handle nonlinear mappings that are not bounded. And we present three different results according to the tape of "continuity" imposed on N : compactness, weak con-

tinuity or type M . As for the linear mapping A we essentially take the same hypotheses as 1. In Section 5 we apply our results to the type of boundary value problem for semilinear elliptic equations discussed in [2].

We would like to thank Prof. L. Nirenberg for supplying us with the preprint of paper [2].

§ 2. Equation with a compact nonlinear part. A mapping $N: X \rightarrow Y$ between two normed spaces X and Y is said to

<u>compact</u> if (i) it is continuous in the norm topologies, and (ii) it takes bounded sets of X into relatively compact sets of Y. In this section we shall study the solvability of the equation

(4) Au + Nu = h,

where \mathcal{H} is a given element in a real Hilbert space \mathcal{H} , and $\mathcal{N}: \mathcal{H} \longrightarrow \mathcal{H}$ is a compact mapping. The main result is as follows.

Theorem 1. Let $A: \mathbb{H} \to \mathbb{H}$ be a bounded linear selfadjoint operator in a real Hilbert space \mathbb{H} , with a closed range $\mathbb{R}(A)$ and a finite dimensional null-space $\mathbb{N}(A)$. Assume that there exists a sequence (\mathcal{A}_m) of positive real numbers in the resolvent set of A, such that $\mathcal{A}_m \to \mathcal{O}$. Let $\mathbb{N}: \mathbb{H} \to \mathbb{H}$ be a compact mapping such that

(5) $\| N u \| \leq c \| u \|^{\alpha} + X$,

for all $\mathcal{U} \in \mathcal{H}$, where c > 0, K > 0, $0 \le \alpha < 1$, are fixed constants. Assume that the following condition holds: (C) Given $y \in \mathcal{N}(A)$, $\|y\| = 1$, and sequences $t_m \to +\infty$, $y_m \to y_r$, $y_m \in \mathcal{N}(A)$, $z_m \in \mathcal{R}(A)$, $\|z_m\| \le K_1$, where K_1 is a constant. we have

(5)
$$(h, y) > \lim_{m \to \infty} \inf (N(t_m y_m + t_m^{\alpha} z_m), y)$$
.

<u>Then equation</u> (4) has a solution $u \in H$.

<u>Remark</u>. If we have " e information that there exists a sequence of negative real numbers $\mathcal{A}_{m\nu}$ in the resolvent set of A, then the inequality (6) is replaced by

- 417 -

(6')
$$(h, y) < \lim_{m \to \infty} \sup \left(\mathbb{N}(t_n y_n + t_n^{\infty} x_m), y \right).$$

<u>Proof</u>: Consider first the approximant equations

(7)
$$Au_n - \lambda_n u_n + Nu_n = h ,$$

which we prove now that it is solvable for each $n\nu$. Indeed, (7) is equivalent to

(8)
$$\mathcal{M}_{m} = (\mathbf{A} - \mathcal{A}_{m})^{-1} (\mathbf{m} - \mathcal{M}_{m})^{-1}$$

The mapping $T: \mathbb{H} \longrightarrow \mathbb{H}$ defined by $Tu = (\mathbb{A} - \lambda_m)^{-1} (h - Nu)$ is compact and

$$\|Tu\| \le c_1(\|h\| + \|Nu\|) - c_2\|u\|^{\infty} + c_3,$$

in view of (5). Thus for $\|u\| = \mathbb{R}$, with \mathbb{R} sufficiently large, we have $\|Tu\| \leq \mathbb{R}$. So, by a version of the Schauder fixed point theorem, T has a fixed point u_m , which is a solution of (7).

Next we claim that the sequence (u_m) is bounded. Suppose for the moment that this has been proved and let us complete the proof. In virtue of the hypotheses on A, we see that $H = N(A) \oplus R(A)$. So let us write $u_m = v_m + w_m$, where $w_m \in N(A)$ and $w_m \in R(A)$. Passing to subsequences we may assume that $w_n \to v$ and $w_m \to w$, where " \to " denotes convergence in the norm and " \longrightarrow " denotes weak convergence. We may also assume that $Nu_m \to g$. So we get from (7) that $Aw_m \to h - g$. Since the mapping A restricted to R(A) is a linear homeomorphism, we obtain that

- 418 -

 $w_m \rightarrow w$. Let us denote u = w + w. So $u_m \rightarrow u$, and from (7) we obtain

Au + Nu = n,

that is, \mathcal{M} is a solution of (4).

In order to complete the proof, let us assume, by contradiction, that $\|u_m\| \to \infty$. Let us write $u_m = v_m + w_m$, where $w_m \in N(A)$ and $w_m \in R(A)$. Denoting by P the orthogonal projection of H onto R(A), we obtain from (7)

(9)
$$Aw_m - \lambda_m w_m + PNu_m = Ph$$
.

Since A restricted to R(A) is a linear homeomorphism we have from (9):

$$\|w_{m}\| \leq c_{4} \left[\|A_{m}\| \|w_{m}\| + c_{5} \|u_{m}\|^{2} + K + \|h\| \right]$$

or

(10)
$$\|w_m\| \le c_5 \|u_m\|^{\alpha} + c_6$$

for *m* sufficiently large. Now, let us denote $U_m = u_m / \|u_m\|$, $V_m = v_m / \|u_m\|$ and $W_m = w_m / \|u_m\|$, so that $U_m = V_m + W_m$. Going to subsequences, if necessary, we may assume in view of the finite dimensionality of N(A) that $V_m \rightarrow v_p$, and, in view of (10), that $W_m \rightarrow 0$. So $U_m \rightarrow v_p$ and $\|v_p\| = 1$. Next, we obtain from (7) that

(11)
$$(AU_m, y) - \lambda_m(U_m, y) + \frac{1}{\|u_m\|} (Nu_m, y) = \frac{1}{\|u_m\|} (h, y).$$

- 419 -

Since A is self-adjoint, $(AU_n, y) = (U_n, Ay) = 0$, because $y \in N(A)$. Thus from (11) it follows that

$$\lambda_m \| u_m \| (\mathbf{u}_m, \mathbf{y}) = (\mathbf{N} u_m - \mathbf{k}, \mathbf{y})$$

so for m sufficiently large we have

(12) $(Nu_m - h, y) > 0$.

Now observe that

 $u_m = \|u_m\| V_m + w_m , \quad w_m = \|u_m\|^{\infty} z_m$

where z_m is bounded in view of (10). Thus, it follows from (12) that

 $\lim \inf (Nu_n, h) \ge (h, y),$

which contradicts condition (C).

§ 3. Equation with a weakly continuous nonlinear part. A mapping $N: H \longrightarrow H$ in a Hilbert space H is said to be weakly continuous if $x_m \longrightarrow x$ then implies that $Nx_m \longrightarrow Nx$.

Theorem 2. Same statement as in Theorem 1, except that the compactness of N is replaced by the soumption that N is weakly continuous.

<u>Proof</u> follows the same steps. The only differences are (i) The fixed point of T is guaranteed by the following well known result. "Let T: $H \rightarrow H$ be a weakly continuous mapping such that the boundary of a ball of radius R centered at the origin is mapped into the ball. Then T has a fixed point". This is a result that can be easily proved by Galerkin approximations, i.e., projection onto finite dimen-

- 420

sional subspaces. (ii) Once the sequence (u_m) has been proved to be bounded, we complete the proof in a simpler way. Namely, going to a subsequence, we may assume that $u_m \longrightarrow u$. Since $Au_m \longrightarrow Au$ and now $Nu_m \longrightarrow Nu$, we pass to the limit in (7), and obtain that this u is a solution of (4).

§ 4. Equation with a nonlinear part of type (M). A mapping $N: H \longrightarrow H$ in a Hilbert space H is said to be of type (M) if the following conditions hold:

 (M_{4}) If a sequence (u_{m}) in H converges weakly to an element u, the sequence $Nu_{m} \rightarrow w$ and $\lim \sup (Nu_{m}, u_{m}) \leq \leq (w, u)$, then Nu = w.

 (M_2) N is continuous from finite dimensional subspaces of H to H endowed with its weak topology. The concept of mappings of type (M) was introduced by Brezis [5] on a more general set up. This class includes all the hemicontinuous monotone mappings and the class of pseudomonotone mappings introduced in [5]. We recall the following results, and refer to [6] for proofs.

Proposition 1. Let N be a mapping of type (M) in the Hilbert space H. Let $A: H \longrightarrow H$ be a bounded linear monotone operator. Then A + N is of type (M).

<u>Proposition 2. Let</u> T: $H \rightarrow H$ <u>be a bounded mapping of</u> type (M). Suppose that T is coercive, that

 $\lim_{\|u\|\to\infty} \frac{(\mathrm{Tu}, u)}{\|u\|} = \infty$

- 421 -

Then the range R(T) of T is all of H .

Now we state and prove the main result of this section.

<u>Theorem 3. Let</u> $A: H \rightarrow H$ <u>be a bounded linear monotone</u> operator in a Hilbert space H, with a closed range R(A), and a finite dimensional nullspace N(A). Let $N: H \rightarrow H$ be a mapping of type (M) such that

(13) $\|Nu\| \le c \|u\|^{\alpha} + K$,

for all $u \in K$, where $c > 0, K > 0, 0 \le \alpha < 1$ are fixed constants. Assume that the following condition holds:

(C_M) Given $y \in N(A)$, ||y|| = 1, and sequences $t_m \to +\infty$, $w_m \to w_r$, $w_n \in N(A)$, $z_m \in R(A)$, $||z_m|| \leq K_1$, where K_1 is a constant, we have

(14)
$$(n, y) < \lim \sup (N(t_n y_n + t_n^{\infty} z_n), y)$$
.

Then equation (4) is solvable in H .

Proof: We use the approximant equations

(15)
$$Au_m + \frac{1}{n}u_m + Nu_m = h ,$$

which we claim is solvable for each m. Indeed, by Proposition 1, the mapping $T = A + \frac{1}{m}I + N$ is of type (M). It follows from the boundedness of A and from (13) that T is bounded. Also from the monotonicity of A and from (13) it follows that T is coercive. So Proposition 2 may be applied, and there is a solution \mathcal{M}_m of(15).

As in the previous theorems one has to prove that the

- 422 -

puence (u_m) is bounded. Let us assume that this is the se and let us complete the proof. Going to a subsequence may assume that $u_m \longrightarrow u$. So $Au_m \longrightarrow Au$, and $Nu_m \longrightarrow h - Au$. On the other hand,

 $(Nu_{m}, u_{m}) = (n - Au_{m} - \frac{1}{m} u_{m}, u_{m}) \leq$ 5) $\leq (n, u_{m}) - \frac{1}{m} \|u_{m}\|^{2} + (Au, u) - (Au_{m}, u) - (Au, u_{m}),$

ere we have used the monotonicity of A . So

$$\lim \sup (Nu_{m}, u_{m}) \leq (h - Au, u)$$

together it allows us to use the fact that N is of type) to get Nu = n - Au. That is u is a solution of (4).

Finally, the boundedness of (u_m) is proved just like . Theorem 1.

§ 5. <u>Application to boundary value problems</u>. We shall idicate now the application of our Theorem 1 to proving the cistence of weak solutions of the Dirichlet problem for the quation

17)
$$\Sigma (-1)^{\lceil \beta \rceil} \mathbb{D}^{\beta}(a_{\alpha\beta}(x)\mathbb{D}^{\alpha}) + \Sigma (-1)^{\lceil \alpha \rceil} \mathbb{D}^{\alpha}(g_{\alpha}(\mathbb{D}^{\alpha})) = f$$
,
 $|\alpha|, |\beta| \leq m$

here f is a given function of $L^2(\Omega)$, Ω a bounded open omain in \mathbb{R}^n . This is exactly the problem discussed by Neas, Fučík and Kučera. Our aim in including this problem here s to illustrate the use of Theorem 1, which we believe proides a quicker proof for the existence of solutions. In a paper under preparation we are able to discuss (17) with more general nonlinear part.

- 423 -

Let us denote by (,) the inner product in L^2 and by $(,)_m$ the inner product in H_0^m . For definition of H_0^m and results on the linear Dirichlet problem see, for example, Friedman [7] or Nečas [8].

A weak solution of the generalized Dirichlet problem for (17) is a function $\mu \in \mathbb{H}_0^m$ such that

$$(18) \sum_{|\alpha|, |\beta| \le m} (\alpha_{\alpha\beta} \mathbb{D}^{\alpha}_{\mu}, \mathbb{D}^{\beta}_{\varphi}) + \sum_{|\alpha| \le n} (\alpha_{\alpha\beta} \mathbb{D}^{\alpha}_{\mu}), \mathbb{D}^{\alpha}_{\varphi}) = (f, g)$$

for all $\varphi \in \mathbb{H}_0^m$.

The following assumptions are made on the linear part:

(A₄) The coefficients $a_{\alpha,\beta}$, for $|\alpha|, |\beta| \leq m$, are bounded measurable real functions defined in Ω . The coeffisients $a_{\alpha\beta}$, $|\alpha| = |\beta| = m$, are uniformly continuous.

 (A_2) The linear operator is uniformly strongly elliptic, i.e., there is a constant c > 0 such that

(19)
$$\sum_{\substack{\alpha \in \beta \\ |\alpha| = |\beta| = m}} \alpha_{\alpha\beta}(x) \xi^{\alpha} \xi^{\beta} \ge c |\xi|^{2m}$$

for $\chi \in \Omega$ (a.e.) and $\xi \in \mathbb{R}^m$.

Under these assumptions, we use the Riesz-Fischer representation theorem to define the operator $A: \mathbb{H}_{a}^{m} \longrightarrow \mathbb{H}_{a}^{m}$ by

(20.
$$(Au, g)_m = \sum_{\substack{|\alpha|, |\beta| \le m}} (a_{\alpha\beta} D^{\alpha} u, D^{\beta} g)$$

for all $\varphi \in H_0^m$, which is linear, bounded, self-adjoint and has a discrete spectrum. Let us assume that 0 is an eigenvalue. It is known that the nullspace of A, N(A) is finite

424 -

dimensional. We shall also assume a hypothesis on the unique continuation of elements in the nullspace of A :

(A₃) The only $w \in \mathbb{N}(A)$ such that $\mathbb{D}^{\infty}w$, for some $|\alpha| \leq p$, vanishes on a set of positive measure is w = 0.

For the non linear part we assume:

 (N_1) The functions $g_{\infty}: \mathbb{R} \longrightarrow \mathbb{R}$ are continuous, and there exist constants $1 \le k < 1$, $K_1 \ge 0$, $K_2 \ge 0$ such that

(21)
$$|g_{\alpha}(s)| \leq X_{1}|s|^{\mathscr{H}} + X_{2}$$

for all $b \in \mathbb{R}$ and all $|\alpha| \leq p$.

$$(N_2)$$
 $2(m-p+1) > m$

Under these assumptions, we use the Riesz-Fischer theorem to define the mapping $\mathbb{N}: \mathbb{H}_o^m \longrightarrow \mathbb{H}_o^m$ by

(22)
$$(\mathbb{N}u, \varphi)_m = \sum_{|\alpha| \leq p} (g_{\alpha}(\mathbb{D}^{\alpha}u), \mathbb{D}^{\alpha}u),$$

which is compact, and there are constants c > 0 and X > 0such that

$$(23) \qquad \| \mathcal{N} \mathcal{U} \|_{m} \leq c \| \mathcal{U} \|_{m}^{\mathcal{R}} + \mathcal{K}$$

for all $u \in \mathbb{H}_c^m$. The compactness of N follows from the compact embedding of \mathbb{H}^m into \mathbb{H}^{m-1} , and estimate (23) can be proved using Cauchy-Schwarz's and Hölder's inequalities.

Now observe that (18) is equivalent to

(24)
$$(Au, \varphi)_m + (Nu, \varphi)_m = (h, \varphi)_m$$
, for all $\varphi \in H_0^m$

- 425 -

where $h \in \mathbb{H}_0^m$ is such that $(h, \varphi)_m = (f, \varphi)$ for all $\varphi \in \mathbb{H}_0^m$. The existence of such an h is guaranteed by the Riesz-Fischer theorem. So the generalized Dirichlet problem is equivalent to the functional equation

$$Au + Nu = h$$

in \mathbb{H}_0^m .

Finally, we make the following assumption on the nonlinear part.

 (N_3) The two limits below exist as extended real numbers, that is, in $\mathbb{R} \cup \{-\infty\} \cup \{+\infty\}$:

$$\lim_{b \to +\infty} g_{\alpha}(b) = g_{\alpha}^{+} \text{ and } \lim_{b \to -\infty} g_{\alpha}(b) = g_{\alpha}^{-},$$

with the following provisals (i) if some g_{∞}^+ is $+\infty$ (resp. $-\infty$) then the corresponding g_{∞}^- is $-\infty$ (resp. $+\infty$), (ii) if some g_{∞}^+ is $+\infty$ (resp. $-\infty$) then any other g_{β}^+ is either finite or $+\infty$ (resp. $-\infty$).

Under assumption (N_3) we see that

(25)
$$\mathcal{L}(nr) = \sum_{|\alpha| \le n} q_{\alpha}^{+} \int \mathcal{D}^{\alpha} r + q_{\alpha}^{-} \int \mathcal{D}^{\alpha} r dr$$

is defined as an extended real number, for each $N \in \mathcal{N}(\mathcal{A})$.

Now state the main theorem of this section

<u>Theorem 4</u>. <u>Asssume</u> (A_1) , (A_2) , (A_3) , (N_4) , (N_2) , (N_3) . <u>Suppose that for each</u> $\alpha \in N(A)$, $\|\alpha\|_m = 4$

$$(f, v) < l(v).$$

Then the generalized Dirichlet problem (18) has a solution $\mu \in \mathcal{H}_{\rho}^{m}$.

<u>Proof:</u> It is enough to use Theorem 1. By the remarks made previously in this section, all the conditions of that theorem, except (C), have been checked. Observe that since 0 is an isolated eigenvalue of A, then we can obtain sequences (A_m) in the resolvent set of A made up of either positive real numbers or negative ones. Now we check condition (C). Let $v \in N(A)$, $||v||_m = 1$, $v_m \to v$, $v_n \in N(A)$, $||v_m|| \le k_3$, $t_m \to +\infty$. Then

$$(27) \quad (\mathbb{N}(t_{m} v_{m} + t_{m}^{k} w_{m}), v)_{m} = \sum_{|\alpha| \neq n} \int \mathcal{G}_{\alpha}(t_{m} \mathbb{D}^{\alpha} v_{m} + t_{m}^{k} \mathbb{D}^{\alpha} w_{m}) \mathbb{D}^{\alpha} v_{m}$$
$$= \sum_{|\alpha| \neq n} [\int_{\mathbb{D}^{\alpha} v_{n} > 0} \mathcal{G}_{\alpha}(t_{n} \mathbb{D}^{\alpha} v_{m} + t_{n}^{k} \mathbb{D}^{\alpha} w_{m}) \mathbb{D}^{\alpha} v + \int_{\mathbb{D}^{\alpha} v_{n} < 0} \text{same expression}]$$

The integrands in the last term of (27) converge pointwisely a.e. to $g_{\infty}^+ \mathbb{D}^{\infty} v$ in $\mathbb{D}^{\infty} v > 0$ and $g_{\infty}^- \mathbb{D}^{\infty} v$ in $\mathbb{D}^{\sigma} v < 0$. Here we have used (N_2) to guarantee that $\mathbb{D}^{\tilde{}} w_m$ is bounded in the supremum norm in view of the Sobolev imbeding theorem. Now using the dominated convergence theorem, in the case of g_{∞}^+ finite, or Fatou's lemma, in the case of a g_{∞}^+ infinite, we obtain

$$\lim_{m \to \infty} (N(t_n v_n + t_n^k w_m), v)_m = \ell(v)$$

So (26) implies condition (C). And the proof of Theorem 4 is complete.

Remarks. i) (26) can be replaced by

for all $N \in N(A)$, $\|N\|_{m} = 1$.

ii) Theorem 4 has, as corollaries, Theorems 3.1 and

3.2 of [2] under less stringent hypotheses.
