# CONGRUENCE REPRESENTATIONS OF JOIN-HOMOMORPHISMS OF DISTRIBUTIVE LATTICES: A SHORT PROOF 

G. Grätzer* - H. Lakser* - E. T. Schmidt ${ }^{* *}$<br>(Communicated by Tibor Katriñák)

#### Abstract

András Huhn proved the following theorem: Let $D$ ) and $E$ be finite distributive lattices, and let $\psi: D \rightarrow E$ be a $\{0\}$-preserving joinhomomorphism. Then there are finite lattices $K$ and $L$, and there is a lattice homomorphism $\varphi: K \rightarrow L$ such that Con $K$ (the congruence lattice of $K$ ) represents $D$, Con $L$ (the congruence lattice of $L$ ) represents $E$, and the mapping ext $\varphi: \operatorname{Con} K \rightarrow \operatorname{Con} L$ (obtained by mapping a congruence of $K$ under $\varphi$ to $L$ as a binary relation and then forming the minimal extension of this binary relation to a congruence relation of $L$ ) represents $\psi$.

In this note, we give a short proof of this theorem. In fact, we prove a much stronger result: for $K$ one can choose any finite lattice whose congruence lattice is isomorphic to $D$.

## 1. Introduction

One of the most persistent problems of lattice theory is the representation problem of distributive algebraic lattices as congruence lattice of lattices. A. P. Huhn in [5] attempted to solve this problem by simultaneous representation of finite distributive lattices as congruence lattices of finite lattices.

[^0]To state Huhn's result, we need a notation. Let $K$ and $L$ be lattices, and let $\varphi$ be a homomorphism of $K$ into $L$. Then $\varphi$ induces a map ext $\varphi$ of Con $K$ into Con $L$ : for a congruence relation $\Theta$ of $K$, let the image $\Theta$ under ext $\varphi$ be the congruence relation of $L$ generated by the set $\Theta \varphi=\{\langle a \varphi, b \varphi\rangle \mid a \equiv b(\Theta)\}$.

The following result was proved by A. P. Huhn in [5] in the special case when $\psi$ is an embedding and was proved for arbitrary $\psi$ in [3] (where you also find for a more complete history of this result):

Theorem 1. Let $D$ and $E$ be finite distributive lattices, and let

$$
\psi: D \rightarrow E
$$

be a $\{0, \vee\}$-homomorphism. Then there are finite lattices $K$ and $L$, a lattice homomorphism $\varphi: K \rightarrow L$, and isomorphisms

$$
\alpha: D \rightarrow \operatorname{Con} K, \quad \beta: E \rightarrow \operatorname{Con} L
$$

with

$$
\psi \beta=\alpha(\operatorname{ext} \varphi)
$$

Furthermore, $\varphi$ is an embedding if and only if $\psi$ separates 0.
Theorem 1 concludes that the following diagram is commutative:

$$
\begin{array}{ccc}
D & \quad \psi & E \\
\cong \downarrow_{\alpha} & & \cong \downarrow \beta \\
\operatorname{Con} K & \xrightarrow{\operatorname{ext} \varphi} & \operatorname{Con} L
\end{array}
$$

In this paper, we give a short proof of this theorem. In fact, we prove the following much stronger version:

Theorem 2. Let $K$ be a finite lattice, let $E$ be a finite distributive lattice, and let $\psi$ : Con $K \rightarrow E$ be a $\{0, \vee\}$-homomorphism. Then there is a finite lattice $L$, a lattice homomorphism $\varphi: K \rightarrow L$, and an isomorphism $\beta: E \rightarrow \operatorname{Con} L$ with $\operatorname{ext} \varphi=\psi \beta$. Furthermore, $\varphi$ is an embedding if and only if $\psi$ separates 0 .

## 2. Preliminaries

Let $M$ be a finite lattice and let $C$ be a finite set; the elements of $C$ will be called colors. A coloring $\mu$ of $M$ over $C$ is a map

$$
\mu: \mathfrak{P}(M) \rightarrow C
$$

of the set of prime intervals $\mathfrak{P}(M)$ of $M$ into $C$ satisfying the condition: if two prime intervals generate the same congruence relation of $M$, then they have the same color; that is,

$$
\mathfrak{p}, \mathfrak{q} \in \mathfrak{P}(M) \text { and } \Theta(\mathfrak{p})=\Theta(\mathfrak{q}) \Longrightarrow \mathfrak{p} \mu=\mathfrak{q} \mu
$$

Since the join-irreducible congruences of $M$ are exactly those that can be generated by prime intervals, equivalently, $\mu$ can be regarded as a map of the set $J($ Con $M)$ of join-irreducible congruences of $M$ into $C$ :

$$
\mu: J(\operatorname{Con} M) \rightarrow C
$$

In this paper, we need the more general concept. A multi-coloring over $C$ is an isotone map $\mu$ from $\mathfrak{P}(M)$ into $P^{+}(C)$ (the set of all nonempty subsets of $C$ ); isotone means that if $\mathfrak{p}, \mathfrak{q} \in \mathfrak{P}(M)$ and $\Theta(\mathfrak{p}) \leq \Theta(\mathfrak{q})$, then $\mathfrak{p} \mu \subseteq \mathfrak{q} \mu$. Equivalently, a multi-coloring is an isotone map of the poset $J($ Con $M)$ into the poset $P^{+}\left(C^{\prime}\right)$.

We will now show that a multi-colored lattice has a natural extension to a colored lattice.

Lemma. Let $M$ be a finite lattice with a multi-coloring $\mu$ over the set $C$. Then there exist a lattice $M^{*}$ with a coloring $\mu^{*}$ over $C$ such that the following conditions hold:
(1) $M^{*}$ is the direct product of the lattices $M_{c}, c \in C$, where $M_{c}$ is a homomorphic image of $M$ colored by $\{c\}$.
(2) There is a lattice embedding $a \mapsto a^{*}$ of $M$ into $M^{*}$.
(3) For every prime interval $\mathfrak{p}=[a, b]$ of $M$,

$$
\mathfrak{p} \mu=\left\{\mathfrak{q} \mu^{*} \mid \mathfrak{q} \in \mathfrak{P}\left(M^{*}\right) \text { and } \mathfrak{q} \subseteq\left[a^{*}, b^{*}\right]\right\}
$$

and the minimal extension of $\Theta(\mathfrak{p})$ under this embedding into $M^{*}$ is of the form

$$
\prod\left(\Theta\left(\mathfrak{p}_{c}\right) \mid c \in C\right)
$$

where $\mathfrak{p}_{c}$ is a prime interval of $M_{c}$ if and only if $c \in \mathfrak{p} \mu$, and $\mathfrak{p}_{c}$ is a trivial interval otherwise (in which case, $\Theta\left(\mathfrak{p}_{c}\right)=\omega_{M_{c}}$ ).

Proof. For $c \in C$, define the binary relation $\Phi_{c}$ on $M$ as follows:

$$
u \equiv v \quad\left(\Phi_{c}\right) \Longleftrightarrow c \nLeftarrow \mathfrak{p} \mu \text { for every prime interval } \mathfrak{p} \subseteq[u \wedge v, u \vee v] .
$$

This relation is obviously reflexive and symmetric. To show transitivity, assume that $u \equiv v\left(\Phi_{c}\right)$ and $v \equiv u^{\prime}\left(\Phi_{c}\right)$, and let $\mathfrak{q}$ be a prime interval in $\left.u \wedge w, u \vee w\right]$. Then $q$ is collapsed by $\Theta(u, v) \vee \Theta\left(c^{\prime}, w^{\prime}\right)$. hence there is a prime intevval $\mathfrak{p}$ in $\|\wedge r \cdot\| \vee r \mid$ or $\operatorname{in} \mid c \wedge w, v \vee w]$ satisfying $\Theta(q) \leq \Theta(p)$. It follows from the

## G. GRÄTZER -- H. LAKSER - E. T. SCHMIDT

definition of multi-coloring that $\mathfrak{q} \mu \subseteq \mathfrak{p} \mu$; since $c \notin \mathfrak{p} \mu$, it follows that $c \notin \mathfrak{q} \mu$. hence $u \equiv w\left(\Phi_{c}\right)$. The proof of the Substitution Property is similar.

For $c \in C$, we define the lattice $M_{c}$ as $M / \Phi_{c}$. A prime interval $\mathfrak{p}$ of $M^{*}==$ $\prod\left(M_{c} \mid c \in C\right)$ is uniquely associated with a $c \in C$ and a prime intertal of $M_{c_{c}}$. We define $\mathfrak{p} \mu^{*}=c$. It is easy to see that $\mu^{*}$ is a coloring of $M^{*}$ orer ('. establishing the first condition.

To establish the second condition, for $a \in M$, define $a^{*}$ so that its $M_{r}$-component be $[a] \Phi_{c}$. The mapping $a \mapsto a^{*}$ is obviously a lattice homomorphism. We have to prove that it is one-to-one. Let $a, b \in M$ and $a \neq b$ : we have to prove that $a^{*} \neq b^{*}$. Let $\mathfrak{p}$ be a prime interval in $[a \wedge b, a \vee b]$. Since $\mu^{*}$ is a multi-coloring, there is a $c \in \mathfrak{p} \mu^{*}$. Obviously, then $a \not \equiv b\left(\bmod \Phi_{\text {, }}\right)$, from which the statement follows.

Finally, the third condition is trivial from the definition of $M^{*}$ and $\mu^{*} . ~ Z$

## 3. Proof of Theorem 2

Let $K, E$, and $\psi$ be given as in Theorem 2 .
Step 1. Since $\psi$ preserves 0 and joins, there is a largest congruence $\Phi$ of $\hbar$ such that $\Phi \psi=0_{E}$. Let $K_{1}=K / \Phi$. The mapping $\psi$ has a natural decomposition, $\psi=\psi_{1} \psi_{2}$, where $\psi_{1}$ : $\operatorname{Con} K \rightarrow \operatorname{Con} K_{1}$ is defined by $\Theta_{\iota_{1}}=\Theta \vee \Phi$. and $\psi_{2}: \operatorname{Con} K_{1} \rightarrow E$ is the restriction of $\psi$ to $[\Phi) \cong \operatorname{Con} K_{1}$. Then $\iota_{2}$ separates () in Con $K_{1}$. It is sufficient to prove Theorem 2 for $K_{1}, E$, and $\iota_{2}$.

Consequently, we need only prove Theorem 2 under the assmuption that !. separates 0 .

Step 2. We define a map $\mu$ of $\mathfrak{P}(K)$ to subsets of $J(E)$ :

$$
\mathfrak{p} \mu=J(E) \cap(\Theta(\mathfrak{p}) \psi] .
$$

$\mu$ is obviously isotone. $\psi$ separates 0 , so $\mathfrak{p} \mu \neq \emptyset$. Therefore, $\mu$ is a multi-coloring of $K^{\prime}$ over $J(E)$. We apply the Lemma to obtain the lattice

$$
K^{*}==\prod\left(K_{r} \mid c \in J(E)\right)
$$

Step 3. Any finite lattice $M$ can be embedded in a finite simple lattice $\overline{1}$ with the same zero and mit. Use such an extension for each ${\underset{y}{c}}^{2}$, to ohtain a simple lattice $\bar{K}_{c}$, then define:

$$
L_{0}=\prod\left(\bar{K}_{c} \mid r \in J(E)\right)
$$

and extend the coloring so that $\overline{K_{r}}$, is also colored $b y\{c\}$. Since $I_{0}$ is a direce product of simple lattices, it follows that $J\left(\operatorname{Con} L_{0}\right)$ is mordered: the congruence
lat tice of $L_{0}$ is a Boolean lattice with $|J(E)|$ atoms. $K$ is a sublattice of $K^{*}$, and $K^{*}$ is a sublattice of $L_{0}$, so we obtain an embedding $\varphi: K \rightarrow L_{0}$.

Finally, we construct a special ideal of $L_{0}$. Let $p_{c}$ be an arbitrary atom of the direct component $\bar{K}_{c}$; then the prime interval $\left[0, p_{c}\right]$ of $L_{0}$ has color $c$. The atoms $p_{c}$, or $c \in J(E)$, generate an ideal $B_{0}$ of $L_{0}$ which is a Boolean lattice sat isfying the following properties:
(1) any two distinct atoms have different colors;
(2) every color $c \in J(E)$ occurs in $B_{0}$.

Step 4. We continue by forming a finite atomistic lattice $L_{1}$ with $E \cong$ ('on $L_{1}$ under the isomorphism $\beta_{1}$. For $L_{1}$, we take the oldest published construction as in [4], except that we use a uniform "tripling" (first done in [2]) as opposed to "doubling" of non-maximals as in [4]. To recap, using the exposition in [1], we construct a partial lattice $P_{1}$ with 0 as follows. For every join-irreducible element $p$ of $E$, we take three atoms $p_{1}, p_{2}$, and $p_{3}$, so that in $P_{1}$ they are the three atoms of a sublattice isomorphic to $M_{3}$ with zero 0 ; and if $p, q \in J(E)$, then $p_{i} \wedge q_{j}=0(0 \leq i, j \leq 3)$. If $q \prec p$ in $J(E)$, then we add the clement $p(q)$ so that $p_{3} \vee q_{i}=p(q) \quad(0 \leq i \leq 3)$. Let $L_{1}$ be the ideal lattice of $I_{1}$. The isomorphism $J(E) \cong J\left(\operatorname{Con} L_{1}\right)$ is given as follows: for $p \in J(E)$, the congruence $\Theta(0, p)$ of $L_{1}$ corresponds to $p$. Let $\beta_{1}$ denote the corresponding isomorphism $\beta_{1}: E \rightarrow \operatorname{Con} L_{1}$.

We consider on $L_{1}$ the natural coloring over $J(E)$ (a prime interval $\mathfrak{p}$ is colored by $\left.\Theta(\mathfrak{p}) \beta_{1}^{-1} \in J(E)\right)$. Note that $L_{0}$ and $L_{1}$ are colored over the same set, $J(E)$. Let $B_{1}$ be the ideal of $L_{1}$ generated by the atoms $p_{2}$ for $p \in J(E)$. Then the ideal $B_{1}$ is a Boolean lattice satisfying the properties (1) and (2) stated in Step 3.

Step 5. We have the lattice $L_{0}$ with the ideal $B_{0}$ and $L_{1}$ with an ideal $B_{1}$. Note that $B_{0}$ and $B_{1}$ are isomorphic finite Boolean lattices with the same coloring. Take the dual $L_{2}$ of $L_{1}$; in this lattice, $B_{1}$ corresponds to a dual ideal $B_{2}$. Again, note that $B_{0}$ and $B_{2}$ are isomorphic finite Boolean lattices with the same coloring. Glue together $L_{0}$ and $L_{2}$ by a color preserving identification of $B_{0}$ and $B_{2}$. The resulting lattice is $L$. The prime intervals of $L$ are colored by $J(E)$, and we have the isomorphism $\beta: E \rightarrow$ Con $L$. Since $L_{0}$ is a sublattice of $L$, we may view $\varphi$ as an embedding of $K$ into $L$.

Step 6. Finally, we have to verify that $\operatorname{ext} \varphi=\psi \beta$. It is enough to prove that $\Theta(\operatorname{ext} \varphi)=\Theta \psi \beta$ for join-irreducible congruences $\Theta$ in $K$.

So let $\Theta=\Theta(\mathfrak{p})$, where $\mathfrak{p}=[a, b]$ is a prime interval of $K$. By the Lemma, $\Theta(\mathfrak{p}) \operatorname{ext} \varphi==\Theta\left(a^{*}, b^{*}\right)$ collapses in $K^{*}$ the prime intervals of color $\leq \Theta \psi$; the same holds in $L_{0}$ and in $L$.

Computing $\Theta \psi \beta$ we get the same result, hence $\Theta(\operatorname{ext} \varphi)=\Theta \psi \beta$, completing the proof.

## G. GRÄTZER - H. LAKSER - E. T. SCHMIDT

## 4. Concluding remarks

The proof in [3] of Theorem 1 gave a slightly stronger result the latticen $K$ and $L$ can be chosen to be atomistic. In our proof, here $K$ can be chosen to be atomistic, but $L$ is not atomistic. However, in his thesis ([7; Lemma 4.18]). M. Tischendorf proved that any finite lattice $L$ can be embedded in a finite atomistic lattice $L^{\prime}$ by an embedding $\varepsilon: L \rightarrow L^{\prime}$ with ext $\varepsilon$ an isomorphism. Consequently, extending $L$ in Theorem 2 by such an $L^{\prime}$, enables us to choose' both $K$ and $L$ atomistic in Theorem 1.

Theorem 2 also yields a substantial simplification of the proof of $\mathrm{H} u \mathrm{~h} n$ s theorem [6] that any algebraic distributive lattice with countably many compact elements is the congruence lattice of a lattice. Let us denote by $S$ the join-semilattice of compact elements of the given algebraic distributive lattice. Huhn observes that $S$ is the direct limit (union) of an increasing countable family $\left(D_{i} \mid i<\omega\right)$ of finite distributive 0 -preserving subsemilattices of $S$. The $D_{i}$ are, of course, distributive lattices. For each $i<\omega$, let us denote by $\psi_{i}: D_{i} \rightarrow D_{i+1}$ the $\{0, \vee\}$-embedding. Huhn constructs a sequence $\left(L_{i} \mid i<\omega\right)$ of lattices with lattice embeddings $\varphi_{i}: L_{i} \rightarrow L_{i+1}$ such that ext $\varphi_{i}:$ Con $L_{i} \rightarrow$ Con $L_{i+1}$ represents $\psi_{i}$. Then, denoting by $L$ the direct limit of the sequence $\left(L_{i} \mid i<\omega\right)$, it follows that Con $L \cong D$. The construction of the $L_{i}$ and $\varphi_{i}$ is the most complicated part of his paper - it comprises everything but the introduction. However, using our Theorem 2, we can proceed in a straight-forward manner. We first represent $D_{0}$ by a finite lattice $L_{0}$, and, inductively, given $L_{i}$, we immediately get a finite lattice $L_{i+1}$ and an embedding $\varphi_{i}: L_{i} \rightarrow L_{i+1}$ with ext $\varphi_{i}$ representing $\psi_{i}$.
